A specimen brought into this market consisted of cylindrical pieces, varying in size from the thickness of a straw to that of the little finger, somewhat bent or contorted, slightly wrinkled longitudinally, with occasional small asperities, internally luteous, externally covered with a thin, brittle, reddish-brown bark, having a light-brown or brownish ash-coloured epidermis. The cortical portion, which was of a resinous character, had a bitter disagreeable taste, somewhat acid and astringent; the luteous part was quite tasteless. The virtues of the root reside almost exclusively in its bark. They are extracted by water and alcohol. Cahanca has been analyzed by several chemists.

PART III. Cabbage-tree Bark.—Cahinca. 1479

4. a yellow colouring matter; and 3. a coloured viscid substance. Rochleder and Hlasiwetz found also caffeotannic acid. By these chemists a tincture, obtained by boiling the bark in alcohol, was precipitated first with a spirituous solution of acetate of lead, and afterwards, having been previously filtered, with the tribasic acetate of lead. The first precipitate consisted chiefly of caffeotannate and a portion of cahinca of lead, the second of cahinca of lead exclusively. To obtain the caffeotannic acid separate, the first precipitate was treated with sulphuretted hydrogen, and afterwards with neutral acetate of lead, and in like manner several times, until at length a pure caffeotannate of lead remained, which, on decomposition, yielded an acid identical with the tannic acid of coffee. The cahinca acid was obtained by treating the second precipitate with sulphuretted hydrogen, and concentrating the resulting liquid. The chemists last mentioned gave as its formula C_{12}H_{10}O_{4} (Chem. Gaz., ix. 121.) Cahanca acid is white, without smell, of a taste at first scarcely perceptible, but afterwards extremely bitter and slightly astringent, of difficult solubility in water, but readily soluble in alcohol, permanent in the air, and unaltered at 212°. It reddens vegetable blues, and unites with the alkalies, but does not form crystallizable salts. It is thought to exist in the root as subcahinca of lime.

Medical Properties. Cahinca is tonic, diuretic, purgative, and emetic. In moderate doses it gently excites the circulation, increases the discharge of urine, and produces evacuations from the bowels; but is rather slow in its operation. It may be made to act also as a diaphoretic, by keeping the skin warm, using warm drinks, and counteracting its purga-
tive ten lener. In some patients it occasions nausea and griping, and in very large doses always acts powerfully both as an emetic and cathartic. In Brazil it has long been used by the natives as a remedy for the bites of serpents; and its Indian name is said to have been derived from this property. According to Martius, the bark of the fresh root is rubbed with water till the latter becomes charged with all its active matters; and the liquid, while yet turbid, is taken in such quantities as to produce the most violent vomiting and purging, preceded by severe spasmodic pains. Patrick Brown speaks of the root of C. racemosa as very useful in obstinate rheumatisms. But the virtues of calinca in dropsy, though well known in Brazil, were first made known to the European public in the year 1826, by M. Langsdorf, Russian Consul at Rio Janeiro. Achille Richard afterwards published a few observations in relation to it in the Journal de Chimie Médicale; and its properties were subsequently investigated by numerous practitioners. M. François, of Paris, contributed more than any other physician to its reputation. It was considered by him superior to all other remedies in dropsy. But general experience has not confirmed the partial estimate of Dr. François; and, having been found at least equally uncertain with other diuretics, the medicine is now little used. It was employed in substance, decoction, extract, and tincture. The powdered bark of the root was given as a diuretic and purgative, in a dose varying from a scruple to a dram; but the aqueous or spirituous extract was preferred. The dose of either of these is from ten to twenty grains. Dr. François recommended that, in the treatment of dropsy, a sufficient quantity should be given at once to produce a decided impression, which should afterwards be maintained by smaller doses, repeated three or four times a day.

CALABAR BEAN. Ordeal Bean of Calabar. It has been long known that certain poisonous substances were used as an ordeal, to determine the guilt or innocence of accused individuals, among the Negroes of Western Africa. One of these, called the ordeal bean of Calabar, from the region where it is used, was brought to the notice of the scientific public by Dr. Daniell, in a paper read before the Ethnological Society of Edinburgh in 1846. Considerable attention was attracted to the subject; and specimens of the bean were obtained by Dr. Christison from the Gold Coast. These were planted in the Botanical Garden at Edinburgh, and produced a plant, which proved to be a perennial creeper, belonging to the natural family Leguminosce; but at the date of the publication of the last edition of this work, early in 1858, the precise botanical position of the plant had not been determined. In the year 1859, specimens of the plant were sent from Calabar, which came under the observation of Dr. Balfour, of Edinburgh, who was thus enabled to ascertain its botanical character. He communicated the results of his examination to the Royal Society of Edinburgh; and his paper is published, with a particular description of the plant, in its Transactions (vol. xxii. p. 305). Having found that the plant belonged to a yet undescribed genus, he established a new one with the title of Physostigma, suggested by a peculiar inflation of the stigma; and designated the species as venenosum, from the notorious qualities of the fruit. The Physostigma venenosum is a climbing plant with a ligneous stem, mounting on trees and shrubs, and frequenting especially the banks of streams, into which it often drops its fruit when ripe; and it is said that the people of Calabar obtain their supply principally from the borders of the river down which the fruits are carried. A description of the plant, taken from that by Dr. Balfour in the Philosophical Transactions, may be seen in the Edinburgh Medical Journal (July, 1863). In the same journal (p. 36) is an essay by Dr. Thos. R. Fraser, containing a summary of what was known on the subject of the bean up to that date, with a particular description of the bean, and an account of experiments made with it on animals. The plant is the only known species of the genus. The seed is about the size of a large horse-bean, being somewhat more than an inch in length by three-fourths of an inch in breadth, with a very firm, hard, brittle, shining integument of a brownish-red, pale-chocolate, or ash-gray colour. The shape is irregularly kidney-form, with a longer convex and a shorter concave edge, two flat sides, and a furrow running longitudinally along its convex margin, and ending in an aperture near one of the extremities of the seed. Within the shell is a kernel consisting of two cotyledons, weighing on an average about 46 grains, hard, white, and pulverizable, of a taste like that of the ordinary edible leguminous seeds, without bitterness, acrimony, or aromatic flavour. The bean yields its virtues to alcohol, and imperfectly to water. Jobst and Hesse are said to have succeeded in isolating the active principle, which they found exclusively in the cotyledons. They obtained it by exhausting an alcoholic extract of the seeds with water, adding magnesia to neutralization, which is indicated by the liquid becoming brown, then concentrating, and treating with ether. The ethereal solution is shaken with a little weak sulphuric acid. The liquid separates into two layers; the upper, ethereal, containing no alkaloid, and the lower, a solution of the sulphate in water. The latter is separated, treated with magnesia, and afterwards with ether, which yields the alkaloid on evaporation. The substance thus obtained they propose to name physostigmin. It is brown, amorphous, soluble in ammonia, soda, ether, benzole, and alcohol, and less so in cold water. Its watery solution has an alkaline reaction, and forms
PART III.

Calabar Bean.

1481

salts with the acids. Iodide of potassium precipitates it of a dark-brown colour. Melted with potassa it yields alkaline vapours. (Journ. de Pharm., Mars, 1864, p. 277.)

The bean is the only part known to possess medicinal properties. The shell is not without some influence on the animal system, as shown by experiments upon rabbits made by Dr. Fraser, who found it to purge, increase the flow of urine, and produce temporary paralysis of the extremities, but without loss of consciousness; and, though a quantity of extract equivalent to a drachm of the shell was given, it did not cause death. The kernel, however, is by far the most active part, as a rabbit was killed by five and a half grains of it. The most prominent effects of this part of the bean were obviously on the spinal marrow, and, as believed by Dr. Fraser, of a depressing character. They were paralysis, loss of reflex action, contraction of the pupil, occasionally evacuation of the bowels, with retention of consciousness until all power of expression ceased. Immediately after death the pupils dilated. No changes of structure were discoverable which could explain the phenomena. The brain and spinal marrow were apparently normal, and the heart full of blood. Similar effects were produced by topical application. The function of the part was suspended. The cardiac action and the vermiform movements of the bowels ceased by contact with the poison: and a little of it applied to the eye, produced contraction of the pupil of that eye, but not of both. The general conclusions of Dr. Fraser were, that the kernel has a depressing action on the spinal cord, causing death by paralysis in some instances of the respiratory muscles, in others of the heart. One of the most interesting results of his experiments appears to be, that the integument of the seed, though possessing in a slight degree the powers of the kernel over the nervous system, differs from it in being actively cathartic.

In reference to the effects of the medicine upon the human system, precise results have not been obtained. It was known that the beans used by the natives as an ordeal, when given in a certain quantity, generally proved fatal, and the individual only escaped when they provoked vomiting, which was rare. A draught containing 19 seeds pounded and infused in water killed a man in an hour. It would be a subject of interesting inquiry, whether the intumescences might not, in certain quantities, act energetically as an emetic as well as cathartic; and whether the escape of the accused person, in some instances, might not be owing to the accidental or contrived exhibition of a larger than ordinary proportion of this part of the seeds. Dr. Christison took about 12 grains of the kernel, which in 15 minutes produced giddiness and a feeling of torpidity, followed by great weakness and faintness, paleness of the surface, extreme weakness and irregularity of the pulse, and indisposition or inability to make voluntary muscular effort. There was no pain or other uneasiness, except the feeling of prostration and some nausea, and the intellect was normal. In two hours after the poison was swallowed, drowsiness occurred, but no stupor. Dr. Fraser experienced from smaller doses effects of a similar character, with temporary dimness of vision. The heart appears to be somewhat variously affected, sometimes acting irregularly or tumultuously, and sometimes less frequently. A peculiar epigastric sensation is generally experienced as the first symptom, about five minutes after the taking of the medicine, gradually increasing, and becoming at length almost painful. This continues at intervals for a considerable time, is after a little while attended with some dyspnoea; and then dizziness and feebleness of the extremities are experienced.

The most interesting effect of the calabar bean, so far as its practical application is concerned, is that of contracting the pupil: an effect resulting whether from its internal or local use. It is most conveniently obtained by introducing a drop of watery solution of the alcoholic extract into the eye. Only the eye operated on is in this case affected. It is highly probable that the effect is produced by a debilitating or paralyzing influence on the spinal centres, whereby the action of the expanding fibres is suspended, and the contractile influence from the cerebral centres is left unimpeded. Another effect on the eye, more recently noticed, is the contraction of the ciliary muscle, which regulates the accommodating power of the organ. Credit is especially due to Dr. D. A. Robertson, of Edinburgh, for calling attention to this influence of the calabar bean. (Ed. Med. Journ., March, 1863, p. 816.) By this influence on the accommodation of the eye, distant objects become indistinct, are apparently magnified, and seem nearer; and Dr. Robertson noticed that this effect was produced sooner and ceased sooner than that upon the pupil. The eye in its normal state thus becomes near-sighted under the influence of the bean. In both these respects there is a strong contrast between the actions of the calabar bean and belladonna; one being exactly antagonistic of the other; as belladonna produces dilatation of the pupil, probably by relaxing the contractile power from the cerebral centres, and at the same time relaxes the ciliary muscles. It does not follow that the operation of the bean is positively stimulant any more upon the ciliary muscles than upon the contractile muscles of the iris. It may in both cases be considered as diminishing or paralyzing a power which in the normal state balances the stimulant influence of the brain. The practical application of these properties of the calabar bean is obvious; and it is now considerably used whenever the indication is presented either for producing contraction of the pupil, or increasing the power of accommodation of the eye to distances.
In regard to the general therapeutic application of the calabar bean less has been decidedly determined. But it would seem to be indicated, if the above views of its mode of action are correct, in all cases of abnormal excitement or irritation of the spinal marrow, especially in tetanus and the poisonous effects of strychnia.

The bean may be used in the form of tincture or alcoholic extract. The dose of the kernel would be two to three grains, to begin with, and increased if necessary. But it is seldom used in this way. A strong tincture may be made by percolation with alcohol, in which five minims shall represent three grains of the bean, and a tincture of this strength is recommended by Dr. Fraser. The same writer obtained about 4 per cent. of extract by exhausting the kernel with alcohol. The dose, therefore, of alcoholic extract should not exceed one-twenty-fourth of that of the kernel, or one-eight of a grain.

For application to the eye Dr. Robertson employed an alcoholic extract mixed with water so as to make liquid preparations of different strengths, one minim representing half a grain, two grains, or four grains. He found these begin to affect the power of accommodation in 10 minutes, and to produce the full effect in 20 or 30 minutes. They were also wholly unirritating to the eye. But they did not keep well, and he afterwards abandoned them for preparations made by suspending the extract in simple syrup. But it would seem best to keep the extract perfectly dry and mix it with a little water when wanted. This extract dissolves freely in glycerin; and a solution of two and a half grains in 100 minims of that liquid perfectly pure has been found to answer in practice. (Pharm. Journ., July, 1863, p. 26.)

Another method of application is to impregnate paper by immersing it three or four times in a concentrated tincture of the bean, allowing it to dry after each immersion, and placing within the lower lid a piece of the paper thus prepared, about one-eighth of an inch square.

W.

CALAMINA. Calamine. Lapis Calaminaris. Calamine is introduced into this part of the Dispensatory, because dismissed from the Pharmacopoeia. The term calamine is applied by mineralogists indiscriminately to two minerals, scarcely distinguishable by their external characters, the carbonate and silicate of zinc. The term, however, in the pharmaceutical sense refers to the native carbonate only. The silicate is sometimes called electric calamine. Calamine is found in the United States, but more abundantly in Germany and England. It usually occurs in compact or earthy masses, or concretions, of a dull appearance, readily scratched by the knife, and breaking with an earthy fracture; but sometimes it is found crystallized. Its colour is very variable; being, in different specimens, grayish, grayish-yellow, reddish-yellow, and, when very impure, brown or brownish-yellow. Its sp. gr. varies from 3-4 to 4-4. Before the blowpipe it does not melt, but becomes yellow and sublimes. When of good quality, it is almost entirely soluble in the dilute mineral acids; and, unless it has been previously calcined, emits a few bubbles of carbonic acid. If soluble in sulphuric acid, it can contain but little carbonate of lime, and no sulphate of baryta. Ammonia, added to the sulphuric solution, throws down the oxide of zinc, mixed with the subsulphate, and takes it up again when added in excess. If copper be present, the ammonia will give rise to a blue colour; if iron, the alkali will throw down the sesquisulphide, not soluble in an excess of the precipitant. The official calamine is distinguished from the electric calamine, which is a silicate of zinc, by dissolving in warm nitric acid without gelatinizing, and by not being rendered electric by heat.

Impurities. According to Mr. Robert Brett, calamine, as sold in the English shops, is frequently a spurious mixture containing only traces of zinc. He analyzed six specimens, and found them to contain from 78 to 87-5 per cent. of sulphate of baryta, the rest consisting of sesquisulphure of iron, carbonate of lime, sulphate (sulphuret) of lead, and mere traces of zinc. When acted on by muriatic acid, the spurious calamine, in powder, evolved sulphuretted hydrogen, and was only in small part dissolved, the great bulk of it remaining behind as sulphate of baryta. (Amer. Journ. of Pharm., ix. 173.) The results of Mr. Brett have been confirmed by Dr. R. D. Thomson, Mr. D. Murdock, and Mr. E. Moore. Dr. Thomson thinks the spurious calamine is made of sulphate of baryta and chalk, coloured with Armenian bole. The late Mr. Jacob Bell, of London, held the more probable opinion that it is the native sulphate of baryta, deriving its colour from iron, which is a mineral having some resemblance to calamine. Mr. Midgley, indeed, states that the miners in England distinguish two calamines, brass calamine, which is sold to the makers of brass, and baryta calamine, which is really the native amorphous sulphate of baryta, and which is furnished to the druggists in the place of the genuine native carbonate of zinc. Even the genuine calamine of the shops is impure, usually containing iron and copper, and various earthy matters. That which has been calcined, to render it more readily pulverized, contains little or no carbonate acid. In view of these facts, the revisers of the U. S. Pharmacopoeia of 1850 deemed it proper to introduce, as a new official, the pure carbonate of zinc, obtained by precipitation. (See Zinc Carbonas Precipitata.) The crystallized variety is anhydrous, and consists of one eq. of carbonic acid 22, and one of protoxide of zinc 40.3 = 62.3. The compact and earthy varieties are said to contain one eq. of water.

Prepared Calamine. Calamina Preparata. Calamine must be impalpable before being used.
in medicine. In this state it forms prepared calamine, which, though but recently an official preparation, has shared the fate of its original, and been discarded from the pharmacopoeia. The following is the U.S. formula of 1850. "Take of Calamine a convenient quantity. Heat it to redness, and afterwards pulverize it; then reduce it to a very fine powder in the manner directed for Prepared Chalk." (U.S.) The object of this process is to bring the native carbonate of zinc, or calamine, to the state of an impalpable powder. It is first calcined, to render it more readily pulverizable, and then levigated and triturated. During the calcination, water and more or less carbonic acid are driven off; so that little else remains than the oxide of zinc, and the earthy impurities originally existing in the mineral. Calamine, as sold in England, is almost always spurious, consisting wholly or principally of native sulphate of baryta, coloured with sesquioxide of iron. The same remark applies to the calamine in the shops of the United States. Of six samples analyzed by Mr. F. Brinthurst, of Wilmington, Del., five were totally devoid of zinc, and the sixth contained only 2 per cent. of the oxide. (Am. Journ. of Pharm., July, 1857.) Prepared calamine is in the form of a pinkish or flesh-coloured powder, of an earthy appearance. Sometimes it is made up into small masses. It is used only as an external application, being employed as a mild astringent and exsiccant in excoriations and superficial ulcerations. For this purpose it is usually dusted on the part, and hence the necessity for its being in very fine powder. It is often employed in the form of cerate. (See Ceratium Calamine, page 1041.) The evidence being conclusive that the powder almost universally sold as prepared calamine is a spurious article, consisting chiefly of sulphate of baryta, whatever therapeutic effects it may have exerted, must be attributed to that salt.

B. CALENDULA OFFICINALIS. Marygold. This well-known garden plant was formerly much employed in medicine. It has a peculiar, rather disagreeable colour, which is lost by drying, and a bitter, rough, saline taste. Among its constituents is a peculiar principle, called calendulin, discovered by Geiger most abundantly in the flowers, and considered by Berzelius as analogous to bassorin, though soluble in alcohol. The plant was thought antispatomodic, sudorific, deobstruent, and emmenagogue, and was given in low forms of fever, scrofula, jaundice, amenorrhoea, &c. Both the leaves and flowers were used; but the latter were preferred, and were usually administered in the recent state, in the form of ten. An extract was also prepared, and employed in cancerous and other ulcers, sick stomach, &c. At present marygold is very seldom if ever used in regular practice.

W. CALLISTRICHNE Verna. (Gray's Manual, p. 384.) Water Starwort. This is a small, herbaceous, indigenous water plant, growing in shallow streams, ditches, or ponds, with a long stem under water, and leaves floating on the surface. This and several other species of the same genus are supposed to have diuretic properties, and are given in decoction in dropsical affections and complaints of the urinary organs.

W. CALOTROPIS GIGANTEA. Brown. Acalypsis gigantea. Linn. Under the name of madar or mudar, a medicine has been employed in the East Indies, with great asserted advantage. It is the bark of the root of a species of Calotropis, generally considered as C. gigantea, but asserted by Dr. Casanova to be a distinct species, and named by him C. Madar 1ndica-orientalis. C. gigantea is a native of Hindostan, and has been introduced into the West Indies, where it is now naturalized. The bark, as employed, is without epidermis, of a whitish colour, nearly or quite imporous, and of a bitter somewhat nauseous taste. It appears to have the general properties of many other aerial medicines; in small doses, increasing the secretions, and in larger, producing nausea and vomiting. According to Dr. Casanova, who published an essay upon the subject at Calcutta, it is especially directed to the skin, the capillaries and absorbtions of which it stimulates to increased action. It is chiefly recommended as a remedy in the obstinate cutaneous diseases of tropical climates, such as elephantiasis and leprosy. It has been employed also in syphilis, dropsy, rheumatism, and hectic fever. It is given in substance in the dose of from three to twelve grains, three times a day, and gradually increased till it affects the system. The plant has of late years been applied to various economical purposes in India, independently of its medical use. The most important of these is the manufacture of cords, ropes, &c. from the fibres of its branches, which are said to possess many of the properties of flax, and to be applicable to the making of cloth. (Chem. News, No. 167, p. 76.)

W. CAM WOOD. A red dye-wood, procured from the Baphia nitida of De Candolle, a leguminous tree, growing on the Western Coast of Africa. The wood is usually kept in the shops in the ground state. It yields its colouring matter scarcely at all to cold water, slightly to boiling water, and readily to alcohol and alkaline solutions. This colouring matter is thought to be identical with sotantil.

W. CANARY SEED. The seeds of Phalarias Canariensis, an annual plant belonging to the grasses, originally from the Canary Islands, but now growing wild in Europe and the United States, and cultivated in many places. The seeds are ovate, somewhat compressed, about two lines long, shining, and of a light yellowish-gray colour externally, and brownish within. Their chief constituent is starch. They were formerly esteemed medicinal, but
Caoutchouc.

PART III.

are now used for emollient cataplasms. They are nutritive, and their meal is said to be mixed, in some places, with wheat flour, and made into bread. They are used as food for Canary birds.

CAOUTCHOUC. Gum Elastic. Indian Rubber. Many lacticose plants belonging to the natural orders Artocarpaceae, Apocynaceae, and Euphorbiaceae, and growing in hot countries, yield products analogous to caoutchouc; but, as found in general commerce, this substance is the concrete juice of different species of Siphonia, especially the *Siphonia Calacchu* of Schreber and Willdenow, identical with Siphonia elastica of Persoon, the *Jatropha elastica* of the younger Linneus, and the *Hevea Guianensis* of Aublet. This is a large tree, growing in Brazil, Guiana, and probably also in Central America (*Journ. of Phil. Col. of Pharm.*, vol. 292); but the product is brought chiefly from the port of Para, in Brazil. On being wounded, the tree emits a milky juice, which concretes on exposure, and constitutes the substance in question. Caoutchouc comes to us in large flat pieces, or moulded into various shapes. The latter are formed by applying successive layers of the juice upon moulds of clay, which are broken and removed when the coating has attained a sufficient thickness and consistence. In the drying of these layers, they are exposed to smoke, which gives to the concrete mass a blackish colour. The juice, when concretes by exposure to the air, assumes on the outer surface a yellowish-brown colour, while the mass remains white or yellowish-white within. It is said that a little alum facilitates the coagulation, while ammonia retards it; so that a little of the latter may be advantageously added, when it is desired to keep the milky juice in the liquid state. (R. Spruce, *Pharm. Journ.*. xv. 118.) The resistant juice contains, according to Faraday, 1-9 per cent. of vegetable albumen, traces of wax, 7-13 per cent. of a bitter azotized substance soluble in water and alcohol, 2-9 of a substance soluble in water but insoluble in alcohol, 50-87 of water with a little free acid, and only 81-7 of the pure elastic principle to which chemists have given the name of caoutchouc. Besides these principles the concrete juice, as it reaches us, generally contains scot derived from the smoke used in drying it. Pure caoutchouc is nearly colourless, and in thin layers transparent. It is highly elastic, lighter than water, without taste and smell, fusible at about 248°, remaining unctuous and adhesive upon cooling, inflammable at a higher temperature, insoluble in water, alcohol, the weak acids, and alkaline solutions, soluble in ether when entirely freed from alcohol, soluble also in chloroform and most of the fixed and volatile oils, though, in the latter, at the expense of its elasticity. It is said, however, that the oils of lavender and sassafras dissolve it without change, and that, when precipitated by alcohol from its solution in cajeput oil, it is still elastic. But its best solvents, for practical purposes, are coal-naphtha or benzine, the empyreumatic oil obtained by distilling caoutchouc itself, and pure oil of turpentine. According to Dr. Bolley, the best method of effecting its solution, for the preparation of a varnish, is first to digest it, cut in small pieces, in bisulphuret of carbon, which converts it into a jelly, and then to treat this jelly with benzine. A larger proportion is thus taken up than by any other method. (See *Am. Journ. of Pharm.*, Sept. 1862, p. 414.) Caoutchouc is not affected by atmospheric air, chlorine, muriatic or sulphurous acid gas, or ammonia. It consists, according to Faraday, of 87-2 parts of carbon, and 12-8 of hydrogen.

By the action of sulphur caoutchouc acquires properties which greatly increase its value in the arts. It becomes of a black colour and horny consistence, preserves its elasticity under the influence both of heat and cold, is compressible with great difficulty, and resists the ordinary solvents, such as petroleum and oil of turpentine. In this state it is said to be *vulcanized*. The discovery of the process of *vulcanization* is ascribed to Mr. Charles Goodyear, of New York. (Chem. Gaz., x. 193.) It consists in submitting caoutchouc in thin sheets to the action of a mixture, composed of 40 parts of bisulphuret of carbon and 1 of chloride of sulphur. For fuller details the reader is referred to the *Journ. de Pharm.* (3e sér., xvii. 205). But the same object may be effected in other methods. When thin layers of caoutchouc are immersed for two or three hours in melted sulphur at the heat of 240° F., they are penetrated by the sulphur, but undergo no change of properties. If now heated in an inert medium to a temperature of from 275° to 320°, a chemical reaction takes place, and the vulcanized product is obtained. The same result takes place if the caoutchouc be first pounded with from 12 to 20 per cent. of finely powdered sulphur, and then heated to the temperature requisite for vulcanization. In either case a portion of unconsumed sulphur remains mechanically mixed with the vulcanized caoutchouc, from which it may be separated by various solvents, such as solutions of caustic soda or potassa, bisulphuret of carbon, oil of turpentine, anhydrous ether, &c. The *desulphurated* product thus obtained, while exempt from the disadvantages arising from the reaction of free sulphur, is more porous than before. (Ibid., xxi. 306.)

Caoutchouc is used for erasing pencil marks; in the formation of flexible tubes for the laboratory, and of catheters, bougies, pessaries, dilaters, and other instruments for surgical purposes; in the melted state, as a luting to the joints of chemical apparatus; in the shape of thin layers, for covering the mouths of bottles, and for other purposes in which the exclusion of air and moisture is requisite; in the manufacture of water-proof cloth:
PART III.

Capparis Spinosa.—Caramanica Gum. 1485

as a varnish, and for numerous other purposes, to which its elasticity, and the resistance which it offers to the ordinary solvents, and to other powerful chemical agents, peculiarly adapt it. It may be brought into the state of thin layers, by softening the small flakes of it in strong containing alcohol, or boiling them in water for a few minutes, and then distending them by means of air forced into them; and the same end may be attained by spreading its naphtha or ethereal solution upon a smooth surface, and allowing the solvent to evaporate. Tubes of caoutchouc may be made from its solution, or from the juice imported in the liquid state. A court-plaster prepared with caoutchouc has been considerably used, and from its impermeability by moisture is sometimes valuable. (See Am. Journ. of Pharm., xv. 38.) A convenient sticking plaster may be prepared by spreading the liquid caoutchouc, by a stiff brush, upon calico, soft leather, or thin sheets of vulcanized Indian rubber as found in the shops. Small thin pieces of caoutchouc may be very advantageously employed to suppress hemorrhage from leech-bites, &c., by first softening one surface of the piece by a taper, and when cool applying it firmly over the bleeding point. The cavity of a decayed tooth may be lined with caoutchouc, so as to prevent the access of air, and thus relieve pain, by fastening a piece firmly around the end of a rod, liquefying the surface by heat, then introducing it with pressure into the cavity, and again withdrawing it. The milky juice obtained from the plant, and prevented from coagulating in the bottle by a little solution of ammonia, has been recommended as a local application in cutaneous eruptions, burns, erysipelas, &c., in which it proves useful by concreting, and forming an elastic covering, impermeable to moisture and the air. A solution of caoutchouc in chloroform is used for the same purpose; the menstruum evaporating quickly, and leaving a thin layer of the elastic substance on the surface. Caoutchouc has been given internally in phthisis, in the dose of one or two grains, gradually increased.

W.

CAPPARIS SPINOSA. Caper-bush. A low, trailing shrub, growing in the south of Europe and north of Africa. The buds or unexpanded flowers, treated with salt and vinegar, form a highly esteemed pickle, which has an acid, burning taste, and is considered useful in scurvy. The dried bark of the root was formerly official. It is in pieces partially or wholly quilled, about one-third of an inch in mean diameter, transversely wrinkled, grayish externally, whitish within, inodorous, and of a bitterish, somewhat acid, and aromatic taste. It is considered diuretic, and was formerly employed in obstructions of the liver and spleen, amenorrhoea, and chronic rheumatism.

W.

CARAMANICA GUM. Under this name a large quantity of a peculiar product was a short time since brought into this market for sale, a specimen of which, kindly sent us by Mr. B. B. Smith, we have had the opportunity of examining. No history of its origin came with it, but, judging from its name and character, we have little doubt that it is identical with the Caramanica gum, noticed under the head of tragacanth, as one of the substances used in the adulteration of that drug. It is in pieces differing in size from that of a small pea to that of a Spanish chestnut, of various shapes, sometimes irregularly spherical, sometimes elongated, often bent or somewhat contorted, occasionally appearing as if several smaller pieces had adhered longitudinally, smoothish on the surface, generally pale, but in some pieces brown, and in most of a faint reddish hue, and translucent in all. The gum is very hard yet brittle, without smell, nearly tasteless, and very gradually softening when held in the mouth. At our request, Professor Procter subjected a portion to examination, and found it, when macerated in cold water, gradually to swell up like tragacanth, and like it, to give up a part of its substance to water, but less than tragacanth. After four or five days it ceased to swell, and the bulky hydrated masses formed appeared like clouded calf's-feet jelly, and with little cohesiveness, in this respect resembling Bassora gum. The dissolved portion was mucilaginous but not thick. It was precipitated by subacetate of lead, but less decidedly than arabin. Oxalate of ammonia caused a white precipitate, indicating the presence of lime. It was not coagulated by borax or sesquichloride of iron, nor was it precipitated by alcohol in flasks like arabin. The undissolved portion, boiled with diluted sulphuric acid, was broken down, assuming a syrupy consistence, and yielded to Trometer's test evidence of the presence of glucose, which must have been formed under the influence of the acid, as the first watery solution contained none. Prof. Procter failed to find any signs of lead on the surface, so that the statement made by Mr. Maltas in relation to the Caramanica gum used to adulterate tragacanth is not applicable to this. But there was no reason to expect it, as this was offered in the market under its own and not a false name. It is very obviously the concrete exuded juice of a tree, but the particular plant which yields it is unknown. So far as examined it corresponds to a considerable extent with Bassora gum: and as it probably comes from Caramanica, a province in the eastern part of Asia Minor, it is not impossible that the two are of the same origin, the Bassora gum being carried down to the Persian Gulf. *

* After the article upon Caramanica gum had been sent to the press, a specimen was shown us, labeled falsa tragacanth, which had been kept for many years in a materia medica cabinet, and had probably been separated from a parcel of adulterated tragacanth, and which so closely resembled the gum described in the text, that we have no doubt of their identity in character and origin. According to Mr. Maltas, Caramanica gum is used in the adulteration of tragacanth to the extent, in different varieties, of from 25 to 100 per cent. (Pharm. Journ., xvi. 20.)
CARANNA. Gum Caranna. A resinous substance, in pieces of a blackish-grey colour externally, dark-brown internally, somewhat shining and translucent, brittle and pulverizable when dry, but, in the recent state, soft and adhesive like pitch, easily fusible, of an agreeable balsamic odour when heated, and of a bitterish resinous taste. (Geiger.) It is said to be derived from the Amyris Caranna of Humboldt, a tree growing in Mexico and South America. Geiger refers it also to Bursera gummifera of the West India Islands; but the resin obtained from this tree is described by the French writers under the name of resin de Gomari, or resin de chibou, or cachabou, and is said to bear a close resemblance to the resin tacomahac.

CARBAZOTIC ACID. Pieric Acid. Nitropropic Acid. This acid is obtained by the action of nitric acid on indigo, silk, and other substances. It may be cheaply prepared from coal tar creosote (impure phenylic acid), or from Australian gum. It is in pale-yellow shining scales, soluble in water, to which it gives a strong yellow colour and very bitter taste. Its salts crystallize readily, and explode when heated. The potassa salt is so sparingly soluble, that an alcoholic solution of the acid may be used as a test for this alkali. Its formula is $C_6(H_3NO_4)O + HO$; being phenylic acid, with three eqs. of hydrogen replaced by three of hypoponitric acid.

From the therapeutic trials, made with carbazotic acid, it is inferred to be tonic and astringent. In large doses it is poisonous; 10 grains of it having been sufficient to kill a dog in less than two hours. (Taylor on Poisons, p. 793.) It was first used in intermittent fever by Dr. Bell, of Manchester, who thought it might be employed as a cheap substitute for quinina. Its salts are preferred to the free acid, which is apt to cause cramps of the stomach; and those most approved are the carbazates of ammonia and iron. Dr. T. Moffat cured several cases of cephalalgia by the iron salt, and cases of intermittent fever and anemia by the ammonia salt. Mr. Alfred Aspland has given an ampie trial to the acid and the salt of amonia, and confirms the statements previously made of their efficacy, having found them especially useful in intermittent fever, and applicable to all cases in which quina is indicated. (Med. Times and Gaz., Sept. 1862, p. 289.) The dose of either, administered in pills, is from a quarter to half a grain, three times a day. Mr. Aspland began with a grain three times a day, and increased to 4 grains for a dose. A curious effect of these salts, first observed by Dr. Moffat, is to produce, in many cases, a temporary yellowness of the skin and conjunctiva, as in jaundice. The effect is generally induced when about 15 grains of the acid have been taken. The urine also becomes orange-coloured. The colour disappears in two or three weeks after ceasing to use the medicine.

Carbazote of iron may be prepared by digesting pure crystallized carbazotic acid with an excess of recently precipitated sesquioxide of iron and water at a gentle heat, till the acid has disappeared, filtering, and evaporating the filtrate at a temperature not exceeding 212°. Thus prepared it is amorphous, reddish-brown in mass, lighter-coloured in powder, of an astringent and intensely bitter and persistent taste, and readily soluble in water. On account of its bitterness, it is best given in pill. (See Am. Journ. of Pharm., March, 1863, p. 169.)

CARBOLIC ACID. Phenic Acid. Phenylic Acid. Phenol. Hydrated Oxide of Phenyl. This substance bears so close a resemblance to creosote, that the two have by some been considered identical; and though they have been proved to be distinct bodies, yet they are often mixed in commerce, and we have been informed that much of what is sold as creosote is really carbolic acid. This name was given to the substance under consideration by Runge, who discovered it, in 1834, in the tar of coal. In 1841, it was thoroughly investigated by Laurent, who, considering it as a hydrated oxide of a peculiar compound radical which he named phenyl ($C_6H_5$), described it under the name of hydrated oxide of phenyl ($C_6H_5-O-\cdot HO$). Its acid properties having been subsequently recognised, it received the name of phenic acid; but chemists appear disposed, out of justice to its original discoverer, to adhere to the title he gave it of carbolic acid. It exists in that portion of coal tar which distils over between 300° and 400° F. This, when mixed with a hot concentrated solution of hydrate of potassa, is resolved, on the addition of water, into a light oil, and a heavier alkaline liquid. If the latter be separated and neutralized with muriatic acid, carbolic acid will be disengaged in an impure state, and will float on the surface in the form of a light oil. By distilling this from chloro of calcium to separate water, and exposing the distillate to a low temperature, carbolic acid coagulates in the form of a colourless crystalline mass disposed to deliquesce, which is to be separated from the accompanying liquid by pressure in bibulous paper. This remains solid at a higher temperature than that required to congeal it; but at 95° it melts, and constitutes the acid in its liquid form. It has been already stated that the congealed acid is disposed to deliquesce. If exposed to the air, it attracts moisture, and rapidly becomes liquid, and continues in this form at ordinary temperatures. As commonly kept in the shops, carbolic acid is a colourless liquid, of an oily aspect, a peculiar empyreumatic odour recalling that of creosote, yet quite distinct, and an acid burning taste. Its sp. gr. is 1.062, and its boiling point 370°. According to M. Lemaire, it is soluble in 20 parts of water. It is freely dissolved by alcohol; and its solubility in water is much increased by the addition of from 5 to 10 per cent. of alcohol or acetic acid. (Lemaire.) Though neutral
Carbolic Acid.—Carburet of Iron.

PART III.

1487

to test-paper, it combines feebly with salifiable bases; its salts being decomposed by carbonic acid, and those with the alkalies having an acid reaction. Heated with ammonia, it yields aniline and water. In antiseptic power, as well as in physiological effects, it has a close analogy with creosote; yet is sufficiently distinguished by its greater sp gr., its much higher congealing and lower boiling point, and by the result of the action of strong nitric acid, which with carbo-fic acid produces pure picric or trinitrophosphoric acid, while with creosote it gives rise to oxalic acid, resinous matter, and but a small proportion of picric acid. (F. Crace Calvert, Lancet, Oct. 31, 1863, p. 523.) Its aqueous solution coagulates albumen, arrests fermentation, instantly destroys the lower forms of vegetable and animal life, and in very small proportion prevents mouldiness in vegetable juices, and protects animal substances against putrefaction. In consequence of this property, also, it is believed by M. Lemaire to have the power of destroying miasms, and even of modifying the matter of contagion. Injected into the rectum it destroys the thread-worm, and thus favours its evacuation. Applied in a pure state to the skin it causes sharp pain, lasting for about an hour; a white appearance is produced, consequent on the coagulation of the albumen, and this is followed by intense inflammation, with exfoliation of the epidermis, continuing for many days. On the mucous surface its action is similar. (Lemaire. See Chem. News, No. 192, p. 66, also No. 194, p. 80.)

Medical Properties and Uses. Much is due to Prof. F. Crace Calvert, of Manchester, England, for bringing into notice this valuable medicine, which was formerly merely one of the refuse matters in the utilization of coal tar. Not only did he first call attention to it; but he has also taken the trouble to collect accounts of its various practical applications, which he has published in the journals, and of which we give a brief abstract. Its most important use hitherto has been as an external remedy. But it has also been used internally with beneficial results. Dr. Henry Browne, of Manchester, has used it advantageously in diarrhoea, and Dr. Roberts has checked vomiting with it, given in the dose of a drop in the form of pill, after creaseat had failed. It has been found to give relief in cases of dyspepsia accompanied with pain in the stomach after meals. Dr. Goddard, of Burslem, has cured a severe case of spasmodic asthma by the acid given with decoction of sarsaparilla. Locally, it may be applied of full strength as a caustic, or variously diluted for different purposes. With reference to its caustic effect, it is peculiarly valuable as affecting only a superficial layer of the surface to which it is applied. Hence it is especially adapted to cases of diphtheritis and malignant angina. It may be used also in anthrax, unhealthy suppuration, and gangrenous or cancerous ulcers, in which its influence in correcting feticd odours renders it peculiarly useful. In hemorrhoidal affections and fistulas it has also proved efficacious. When required to be diluted, it may be dissolved in glycerin, which takes it up in all proportions. Diluted in this way it has been used in the form of ointment, with very good effects. To the same affection it may be applied in the form of ointment, made with 4 parts of carbo-fic acid to 56 of spermaceti. An emulsion of it may be prepared by mixing one part of the acid with 8 parts of sweetened water containing 17 5 per cent. of sugar. A watery solution, made with one part of the acid to 40 parts of hot water, well shaken and then filtered, may be used as an alterative and disinfectant in all fetid ulcers and abscesses, gangrenous wounds, and cases of caries or necrosis, in which it may be injected through the fistulous openings. In many cutaneous eruptions, as lepra, porrigo, and the advanced stages of eczema and impetigo, it has proved efficacious. Should the acid be in the solid state, it may readily be melted by placing the bottle containing it in hot water. (Pharm. Journ., Dec. 1861, p. 319, and Journ. de Pharm., Mars, 1863, p. 250.) M. Bazin employs, with great success, a solution of 1 part of carbo-fic acid in 40 parts of acetic acid of 8° B. and 100 of water, against tetter and the itch, in the former applying a compress wet with the solution daily, in the latter using it simply as a lotion. One application is sufficient to destroy the psora insect. Carbonic acid has also been used to prevent putrefaction in organic substances; and, according to M. Lemaire, the corpse of a man can be preserved by less than 50 centimes (7 5 grains) of the acid. For internal use the dose may be a drop. (Journ. de Pharm., Juillet, 1861, p. 67.) M. Bobœuf prefers the salts of carbo-fic acid to the acid itself. He has found the carbonate of soda or potassas, in a solution of from 5° to 10° B., applied by means of compresses to bleeding wounds, to suppress the hemorrhage instantly. (Ann. de Thérope., 1862, p. 62.)

CARBONIC OXIDE. Dr. Ozanam has proposed this gas as an anaesthetic; his opinion of its fitness being founded on twenty-five experiments on rabbits, and five on man; but his results show it to be dangerous, on account of the sudden manner in which it sometimes acts, and its supposed advantages are problematical. (See B. and F. Medico-Chir. Rec., Am. ed, July, 1857, p. 176.)

CARBURET OF IRON. Ferri Carburetum. Plumbago. Black Lead. This substance has been used both internally and externally in cutaneous affections. For medicinal use it is reduced to very fine powder, and purified by being boiled in water, and digested with dilute nitromuriatic acid. The dose is from five to fifteen grains or more, three or four times a day, given in the form of powder or pill. The ointment is made by mixing from two to six drachms with an ounce of lard.
CARDAMINE PRATENSIS. Cuckoo-flower. This is a perennial herbaceous plant, with a simple, smooth, erect stem, about a foot in height. The leaves are pinnate: the radical, composed of roundish irregularly toothed leaflets, those of the stem alternate, with leaflets which become narrower, more entire, and pointed as they ascend. The flowers are purplish-white or rose-coloured, and terminate the stem in a raceme approaching the character of a corymb. The plant is a native of Europe, and is found in the northern parts of our continent, about Hudson's Bay. It is a very handsome plant, abounding in moist meadows, which it adorns with its flowers in the months of April and May. The leaves are bitterish, and slightly pungent, resembling in some measure those of water-creeses, and like them supposed to be possessed of antiscorbutic properties. In Europe they are sometimes added to salads. The flowers have the same taste as the leaves, and, when fresh, a somewhat pungent odour. When dried they become inodorous and nearly insipid. They formerly possessed the reputation of being diuretic, and, since the publication of a paper by Sir George Baker, more than half a century ago, have been occasionally used as an antispasmodic in various nervous diseases, such as chorea and spasmodic asthma, in which they were successfully employed by that physician. They produce, however, little obvious effect upon the system, and are not employed in this country.

CARYA. Hickory. Juglans, Linn. Several species of the genus Carya, of Nuttall, separated by that botanist from the Juglans of Linnaeus, grew within the limits of the United States, of which C. oliviformis bears the pecan-nut of the South-West, C. abia, the fruit so well known by the name of shell-bark, derived probably from the ragged state of the bark of the stem, C. vulgaris, another variety of shell-bark, and C. tomentosa, the common thick-shelled hickory nut. Other indigenous species are C. amara, C. glabra, and C. microcarpa. The leaves of most if not all of these trees are somewhat aromatic and astringent, and the bark astrigent and bitter; and both no doubt possess medical virtues. Attention has recently been called to them by Mr. Frederick Stearns, of Detroit, in a paper on the medical plants of Michigan, read before the American Pharmaceutical Association, and published in their Proceedings (1859, p. 249). Mr. Stearns bases his opinion of the probable virtues of these products upon a communication made to him by Mr. Caffinbury, of the same State, who had found great advantage from chewing the inner bark of the hickory in dyspepsia, and has used a tincture made from the same bark with great success in the treatment of intermittent fever. The use of the remedy had extended in his neighbourhood, and many employ it habitually in the same complaint, some of whom very wisely prefer the infusion to the tincture, as it has been found equally effectual.

CASTANEA. Chinquapin. This held a place in the secondary catalogue of our Pharmacopoeia, until the late revision, when it was discarded. It is the bark of Castanea pumila, or chinquapin, of our Atlantic States. We present here the short account of it formerly contained in the first part of this work. The genus Castanea belongs to Monocotyledonidea of the Linnaean system, and to the natural order Cupuliferae, with the following generic character:

—"Male. Ament naked. Calyx none. Corolla five-petalled. Stamens ten to twenty. Female. Calyx five or six leaved, maricate. Corolla none. Germ three. Stigmas pencil formed. Nuts three, included in the cleft calyx." (Wald.)—The chinquapin is a shrub or small tree, which, in the Middle States, rarely much exceeds seven or eight feet in height, but, in the Carolinas, Georgia, and Louisiana, sometimes attains an elevation of thirty or forty feet, with a diameter of trunk equal to twelve or fifteen inches. The leaves are oblong, acute, mucronately serrate, and distinguished from those of the chestnut, which belongs to the same genus, by their whitish and downy under surface. The barren flowers are grouped upon axillary peduncles, three or four inches long; the fertile amens are similarly disposed, but less conspicuous. The fruit is spherical, covered with short prickles, and encloses a brown nut, which is sweet and edible, but differs from the chestnut in being much smaller, and convex on both sides. The tree extends from the banks of the Delaware southward to the Gulf of Mexico, and south-westward to the Mississippi. It is most abundant in the southern portions of this tract of country. The bark is the part used. It is astrigent and tonic, and has been employed in the cure of intermitents.

CATALPA CORDIFOLIA. Bignonia Catalpa. Linn. Catalpa tree, or Catawba tree. This is a beautiful indigenous flowering tree, occasionally cultivated for ornamental purposes. It is reputed to be poisonous. The seeds have been employed by several practitioners of continental Europe in asthma. M. Automarchi recommends a decoction, made by boiling twelve ounces of water with three or four ounces of the seeds down to six ounces, the whole to be given morning and night; but, if there be any foundation for the prevalent opinion as to the poisonous character of the tree, this might be a hazardous dose; and it would be advisable, in any one who might be disposed to imitate the practice, to begin with much smaller doses, and to increase until the effects of the medicine on the system are ascertained.

CAULOPHYLLUM THALICTRIODES. (Michaux.) Leoncito thallicotroides. Linn. Blue Cohosh. Pappoose Root. (Gray's Manual, p. 20.) An indigenous, perennial, herbaceous plant,
with matted, knotty rhizomes, from which rises a single, smooth stem, about two feet high, naked till near the summit, where it sends out a large triternately compound leaf, and ending in a small raceme or panicle of greenish-yellow flowers, at the base of which is often a smaller bipinate leaf. The whole plant when young, as well as the seeds, which are about as large as peas, is glaucous. It is the only known species of the genus. It is found in most parts of the United States, growing in moist rich woods. The root is the part used. This has a sweetish, pungent taste, and yields its virtues to water and alcohol. It is deemed especially emmenagogue, and is thought also to promote the contractions of the uterus, for which purpose, we learn, it is much employed by the "eclectic" practitioners, who consider it also possessed of diaphoretic and various other remedial properties. It is given in decocition, infusion, or tincture; the first two being made in the proportion of an ounce to a pint of water, the last of four ounces to a pint of spirit. The dose of the decoction or infusion is one or two fluidounces, of the tincture one or two fluidrachms.

**CEANOTHUS AMERICANUS. New Jersey Tea. Red-root.** A small indigenous shrub, growing throughout the United States. The root is astringent, and imparts a red colour to water. It is said to be useful in syphilitic complaints, in which it is given in the form of decoction, made with two drachms of the root to a pint of water. Schoepf states that it is purgative. The leaves were used during the revolutionary war as a substitute for tea. Dr. Hubbard recommends a strong infusion of the dried leaves and seeds, as a local application in aphthous affections of the mouth and fauces, and the sorethroat of scarlatina, and as an internal remedy in dysentery. (*Boston Med. and Surg. Journ.*, Sept. 30, 1835.)

**CEDRON.** The seeds of a tree growing in New Granada and Central America, and described by M. Planchon under the name of Simaba Cedron, in the *London Journal of Botany* (v. 566), from specimens sent by Mr. Wm. Purdie, curator of the Botanical Garden at Trinidad, to Sir Wm. J. Hooker. Mr. Purdie had received the first intimation of the value of this medicine from Dr. Cespedes, a physician of Bogota. The first account of it, however, which reached Europe appears to have been that of Dr. Luigi Rotellini, a physician of St. Domingo, who had previously resided in New Granada. It was published in an Italian journal so early as the year 1816. In France it appears to have been made known through M. Jamord, who received information of its effects from M. Herran, Chargé d'Affaires in France of the Republic of Costa Rica. The fullest account that we have seen of the plant and its product is from the pen of Sir Wm. J. Hooker. (See *Pharm. Journ.*, Jan. 1851, x. 344.)

*Simaba Cedron* belongs to the natural family of Simarubaceae. It is a small tree, with an erect stem, not exceeding six inches in diameter, branching at top in an umbellate form, with large, glabrous, pinnate leaves, and pale-brown flowers, in long, branching racemes. The fruit is a large, solitary drupe, containing a single seed. The whole plant appears to be impregnated with a bitter principle, but it is the seed only that is used. A specimen of the dried fruit was kindly sent to the author from Cartago, in Costa Rica, by Dr. Guier, formerly of Philadelphia. It is light, of a yellowish-ash colour, flattened-ovate, with one edge convex and the other nearly straight, the convex outline terminating at each end in an obtuse point, of which that at the apex is most prominent. It is about two inches long, and sixteen lines in its greatest breadth. Within, the seed is loose and movable. The seed itself is about an inch and a half long, ten lines broad, and half an inch thick. It is convex on one side, flat or slightly concave on the other, and presents an oval scar near one extremity of the flat surface. It is hard and compact, but may be readily cut with a knife.

Cedron seed is inodorous, but of a pure and intensely bitter taste, not unlike that of quassia. It yields its virtues to water and alcohol. M. Lewry obtained from it a crystalline substance, intensely bitter, freely soluble in boiling water, and neutral to test paper, which he supposed to be the active principle, and proposes to name cedrin. He obtained it by first exhausting the cedron with ether, then treating it with alcohol, and crystallizing from the tincture. (*Journ. de Pharm.*, x. ix. 335.)

This medicine has long had great reputation in New Granada and Central America, as a remedy for the bite of serpents, being mentioned in the *History of the Buccaneers*, published in 1699, as useful for this purpose; and such continues to be the confidence of the natives in its virtues, that they have no fears of the poisonous bite of these reptiles, if provided with the antidote. It is also highly esteemed for the prevention of hydrophobia, and in the treatment of intermittent fever, esضم of the stomach and bowels, and dyspeptic affections. Dr. Guier informed us that he had seen it once apparently successful in curing the bite of a poisonous serpent, and had used it effectually in cholera morbus, colic, and delirium of the face. In the hands of Dr. J. B. Thompson, of London, it has proved useful in gout. (*Med. Times and Gaz.*, April, 1852.) Dr. S. S. Purple, of New York, has found it promptly effectual in a number of cases of intermittent fever, and believes it to possess valuable antiperiodic properties. (*N. Y. Journal of Med.*, N. S., xiii. 173.) To us the medicine appears to be closely analogous to quassia, with which it is botanically allied. The dose used in Central America is one or two grains. M. Herran states that he had employed the remedy in eight cases of poisoning, and that his mode of using it was to administer five
Celastrus Scandens.—Centaury.

PART III.

or six grains with a spoonful of brandy, and to dress the bite with the tincture. He had rarely occasion to repeat the dose to effect a cure. Dr. Botellini says that it is poisonous in overdoses, and has occasioned death in the quantity of twenty-five or thirty grains. A vinegar has been prepared in London by macerating for seven days two scrupules of the cer ton in an ounce of distilled vinegar. The dose is from twenty minims to a fluid drachm. (Pharm. Journ., xii. 63.) From the statements of Dr. Purple, it appears that the doses above stated are too small, and that, from any ordinary quantity, no fear of injurious consequences need be entertained. He gave from ten to thirty grains every four hours, and states that though, in very large doses, it may produce griping and diarrhoea, these effects are easily controlled.

Celastrus Scandens. Climbing Staff-tree. A climbing indigenous shrub, growing from Canada to Carolina, and said to possess emetic, diaphoretic, and narcotic properties. The bark is the part employed. It has been used in chronic affections of the liver and secondary syphilis. For a full description of the plant, see Darlington's Flora Centriae, p. 149. Other species of Celastrus, growing in various parts of the world, have been employed in medicine, though with little reputation.

Centauraea Benedicta. Blessed Thistle. Cenodus benedictus. Cnicus benedictus. (De Cand.) This is an annual herbaceous plant, the stem of which is about two feet high, branching towards the top, and furnished with long, elliptical, rough leaves, irregularly toothed, barred with sharp points at their edges, of a bright-green colour on their upper surface, and whitish on the under. The lower leaves are deeply sinuated, and stand on footstalks; the upper are sessile, and in some measure decurrent. The flowers are yellow, and surrounded by an involucre of ten leaves, of which the five exterior are largest. The calyx is oval, woolly, and composed of several imbricated scales, terminated by rigid, pinnate, spinous points. The plant is a native of the south of Europe, and is cultivated in gardens in other parts of the world. It has become naturalized in the United States. The period of flowering is June, when its medicinal virtues are in greatest perfection. The leaves are the officinal portion. They should be gathered when the plant is in flower, quickly dried, and kept in a dry place. The herb has a feeble unpleasant odour, and an intensely bitter taste, more disagreeable in the fresh than the dried plant. Water and alcohol extract its virtues. The infusion with cold water is a grateful bitter; the decoction is nauseous, and offensive to the stomach. The bitterness remains in the extract. The active constituents are volatile oil, and a peculiar principle for which the name of centin has been proposed. This is crystallizable, inodorous, very bitter, neither acid nor alkaline, scarcely soluble in cold water, more soluble in boiling water, and soluble in all proportions in alcohol. It consists of carbon, hydrogen, and oxygen, and is analogous to salicin in composition. In the dose of 4 or 5 grains, it is said often to vomit, and in that of 8 grains, to be useful in intermittent fevers. (Ann. de Thérap., 1849, p. 206.) The blessed thistle may be so administered as to prove tonic, diaphoretic, or emetic. The cold infusion, made with half an ounce of the leaves to a pint of water, has been employed as a mild tonic in debility of the stomach. A stronger infusion, taken warm while the patient is confined to bed, produces copious perspiration. A still stronger infusion or decoction, taken in large draughts, provokes vomiting, and has been used to assist the operation of emetics. The herb, however, is at present little employed, as all its beneficial effects may be obtained from chamomile. The dose of the powder as a tonic is from a scruple to a drachm, that of the infusion two fluidounces.

Attention has recently been called to another species, Cardus or Cnicus marianus, which was of old used for the same purposes as the C. benedictus, under the impression that its seeds have valuable haemostatic properties. Rademacher is stated to have found a decoction of the seeds of great use in hemorrhages, particularly when connected with diseased liver or spleen. Dr. Lobach considers no other remedy so efficacious in uterine hemorrhage and melan. He has also found it useful in amenorrhoea when connected with derangement of the portal circulation. He gives the seeds in decoction, made in the proportion of two ounces to the pint of water, of which the dose is a tablespoonful every hour. (See Am. Journ. of Med. Sci., April, 1859, p. 587.)

Centaurya. Common European Centary. Centaurium. This long used remedy, which held a place in the Edinburgh Pharmacopoeia even to its latest edition, has been omitted in the British Pharmacopoeia. It consists of the herb, and more especially of the flowering heads of Erythrea Centuria (Persoon), Chironia Centarium (Willd. Sp. Plant. i. 1068). It is a small, annual, herbaceous plant, rising about a foot in height, with a branching stem, which divides above into a dichotomous panicle, and bears opposite, sessile, ovate-lanceolate, smooth, and obusely pointed leaves. The flowers are of a beautiful rose colour, standing without peduncles in the axis of the stems, with their calyx about half as long as the tube of the corolla. The plant grows wild in most parts of Europe, adorning the woods and pastures, towards the close of summer, with its delicate flowers.

The herb, though without odour, has a strong bitter taste, which it imparts to water and
alcohol. The flowering summits are the officinal part. We have seen no satisfactory analysis of this plant. Among its constituents is a bitter extractive matter, for which the name of centaurin has been proposed. But it can scarcely be considered as a pure proximate principle. The fresh herb yields by distillation an odorous watery product, of sharp taste (Geiger, ii. 482), in which M. Méha, a French pharmacist, has detected vaeranionic acid. The same chemist claims to have discovered a peculiar colourless crystallizable, non-nitrogenous substance, which he names erythroceutaurin. He obtained it by exhausting the tops with water, evaporating a portion of the water, allowing the residue to stand, separating the precipitated matter or apotheme, adding alcohol to the remaining liquid which now deposited a bitter substance, and, after the separation of this by decantation, evaporating the liquid to the consistency of syrup, and treating the residue with ether. The etheral solution, upon evaporation, yielded the erythroceutaurin in crystals. These are needle-shaped, soluble in the ordinary menstruum, and possessed of the remarkable property of being strongly reddened by exposure to solar light, and reacquiring their colourless character upon being again dissolved and crystallized. The bitter substance above mentioned may be separated by menstruum into two, one scft and the other dry, the former of which it is that gives its strong smell to the distilled water. Beside these principles, M. Méha found also in centaury a waxy-like substance, and saline matter. (Journ. de Pharm., xliii. 38.)

**Medical Properties and Uses.** The common centaury of Europe has tonic properties very closely resembling those of gentian, with which it is associated in the same natural family. It is employed on the other side of the Atlantic in dyspeptic complaints, and formerly had considerable reputation in the treatment of fever. It was one of the ingredients of the Portland powder. In the United States it has been superseded by Sabattia angularis, or American centaury. The dose of the powder is from thirty grains to a drachm. Another species of Erythrea (E. Chilenensis) possesses similar properties, and is employed to a considerable extent in Chili as a mild tonic. An elaborate account of it may be seen in the Journal de Pharmacie (Seièr., xxv. 434).

**CEPHALANTHUS OCCIDENTALIS. Button-bush.** (Gray's Manual, p. 172.) A very common indigenous shrub, which received both its generic title and common name from the arrangement of its flowers in dense spherical heads (œcalyoW head, and d^ovoc, flower). It prefers moist places, as along streams or in the edges of swamps. Its bark is bitter, is said to be laxative as well as tonic, and has been given in periodical fevers, in decoction or infusion.

**CERIUM.** The salts of this metal have within a few years been brought under notice as medicines by Prof. Simpson, of Edinburgh. The only ones as yet tried are the nitrate and oxalate of the protoxide. For a paper by Prof. F. F. Mayer, of N. York, on the oxalate, describing the method of preparing it from the mineral cerite, which contains the metal in the form of oxide, the reader is referred to the Am. Journ. of Pharm. for Jan. 1860 (p. 1). As obtained by Prof. Mayer, it is the oxalate of the protoxide, and is in the form of a white granular powder, without smell or taste, insoluble in water, alcohol, or ether, but readily dissolved by sulphuric acid. Prof. Simpson conceives that the nitrate of cerium acts as a sedative tonic, resembling in its operation the nitrate of bismuth and the nitrate of silver. He has given it with decided advantage in cases of chronic ulcer of the stomach, in irritable dyspepsia with gastrodynia and pyrosis, and in chronic vomiting and the vomiting of pregnancy. He has found the oxalate of cerium more successful in this last affection than any other remedy that he has employed. (Med. Times and Gaz., Sept. 1859, p. 280.) It has been used also by Dr. Charles Lee, of N. York, who has found it successful not only in the vomiting of pregnancy, but in that attendant on various other affections, as phthisis, hysteria, pyrosis, and atonic dyspepsia. (Am. Journ. of Med. Sci., Oct. 1860, p. 393.) When in Edinburgh in the autumn of 1860, we were informed by Prof. Simpson, that he considered oxalate of cerium as a good nervous tonic, and almost a specific in choreas. The dose is a grain, given twice or thrice a day, dissolved in water.

**CHELIDONIUM MAJUS. Celandine.** A perennial herbaceous plant, growing wild in this country, about old houses and in rocky places; but supposed to have been introduced from Europe, where it is indigenous. It is one or two feet high, bears pinnate leaves and small peduncled umbels of yellow flowers, and, when wounded, emits a yellow, opaque juice. The whole plant is used. It has a faint unpleasant odour, and a bitter, acid, durable taste, which is stronger in the roots than in the leaves. The odour is nearly lost by drying, but the taste remains. The yellow juice is bitter and exceedingly acid, and when applied to the skin produces inflammation and even vesication. The plant, analyzed by MM. Chevallier and Lassaigne, afforded a bitter resinous substance of a deep-yellow colour; a kind of gum-resin of an orange-yellow colour, and bitter, nauseous taste; mucilage; albumen; and various saline substances, besides free malic acid and silica. Dr. Probst, of Heidelberg, afterwards found in it a peculiar acid denominated chelidonic acid; two alkaline principles, one of which forms neutral salts with the acids, and is called chelerythin (chelerythria) in consequence of the intense redness of its salts, the other unites
with but does not neutralize the acids, and is named chelidonin (chelidonia); and lastly a
neuter, crystallizable, bitter principle, which from its yellow colour he calls chelidozanthin.
Chelerythrin appears to be an acid narcotic poison. (Annal. der Pharm., xxix. 113.) It has
been shown by Dr. James Schiels, of St. Louis, to be identical with sanguinarina, and may
be prepared in the same manner. (See Sanguinaria, page 703.) Zwenger has lately iso-
lated another acid, which he names chelidonic acid. (See a paper by Mr. J. M. Maisch, in
the Am. Journ. of Pharm., Jan. 1861, p. 7.)

Celandine is an acid purgative, possessed also of diuretic, and perhaps diaphoretic and
expectorant properties. In overoses, it produces unpleasant effects, and is by some con-
sidered poisonous. By the ancients it was much esteemed as a remedy in jaundice; and
it has been found useful in the same complaint by some modern physicians. It was the
chief ingredient of the old decoctum ad ictericos of the Edinburgh Pharmacopoeia. It has
been given also in other complaints, especially those of a scrofulous character, affecting
the mesenteric and lymphatic glands, the skin, and the eyes. The yellow juice is often
applied to corns and warts, which it destroys by stimulating them beyond their vital
powers, and is said to be very useful in eczema, urticaria, and other itching eruptions.
The fresh herb is also applied locally about the pelvis, with asserted benefit, in amenor-
RHAE, and is much used in the south of Europe as a vulnerary. The dose of the dried
root or herb is from thirty grains to a drachm, that of the fresh root one or two drachms;
and the same quantity may be given in infusion. The watery extract and expressed juice
have also been employed. The dose of the former is from five to ten grains, of the latter
from ten to twenty drops, to be gradually increased.

CHELONE GLABRA. Snake-head. Turtle-head. (Gray’s Manual, p. 285.) This is a very
common indigenous, perennial, herbaceous plant, a foot or two in height, readily distin-
guished by its conspicuous closely clustered flowers, the shape of which, from their resem-
bliance to the head of a snake or tortoise, has given origin both to the common and scientific
names of the plant. It prefers low wet places. The leaves have a bitter taste, and are said
to be tonic and aperient, with a supposed peculiar action on the liver. The decoction, made
in the proportion of two ounces of the fresh herb to the pint, may be given in the dose of
one or two fluidounces.

CHELTENHAM SALT, ARTIFICIAL. Several artificial mixtures have been prepared,
professing to be exact imitations of the saline ingredients in the chalybeate Cheltenham
water; but the only ones which appear worthy of confidence are those prepared by Robert
Alsop, chemist, of London, and W. Hodgson, jun., druggist, of this city. The composition
of the natural Cheltenham chalybeate is given at page 131. The imitation of Mr. Alsop,
as analyzed by Dr. Faraday, contains the same solid and gaseous constituents as the natural
water, except the sulphate of lime, which is very properly omitted; and in the same pro-
portions precisely, with the exception that there is about twice as much free carbonic acid
in the artificial preparation. The iron is present in the state of protoxide, and is imme-
diately dissolved by the free carbonic acid, upon adding a sufficient quantity of water.
The carbonic acid probably exists in a free state in a dry mixture; as there is no obvious
agent present to cause it to be disengaged in the mere act of solution.

Mr. Alsop’s artificial mixture is in the form of a powder, nearly white, possessing a saline
and slightly ferruginous taste. It forms a good combination, in which the aperient
property of the salts present is combined with the tonic virtue of the iron. It is considered
to be useful in glandular obstructions, especially of the liver, and in scrofulous affections,
attended with feeble digestion, sluggish bowels, and pallidness of skin. It is employed,
also, with advantage in sick headache, habitual costiveness, and hemorrhoids. The dose is
a teaspoonful, quickly dissolved by brisk stirring in half a pint of cold water, and swal-
lowed immediately, before the iron has time to separate in an insoluble state. This quantity
may be taken in the morning, fasting, and repeated once or twice after an interval of twenty
minutes, or in the course of the day. To obtain its full tonic and alterative effects, it should
be persevered with for a month or six weeks. The artificial Cheltenham salt of Mr. Hodgson
is identical with that of Mr. Alsop, and may be used with entire confidence for all the pur-
poses to which the latter is applied.

CLORIDE OF ARSENIC, SOLUTION OF. Liquor Arsenici Chloridi. De Valangin’s Ar-
senical Solution. The following formula was given for this preparation in the late London
Pharmacopoeia. “Take of Arsenious Acid, broken into small pieces, half a drachm; Hydro-
chloric Acid a fluid drachm and a half [Imperial measure]; Distilled Water a pint [Imp.
meas.]. Boil the Arsenious Acid with the Hydrochloric Acid, mixed with a fluidounce
[Imp. meas.] of the Water until it is dissolved; then add sufficient Water to make the
solution accurately fill the measure of a pint [Imp. meas.].” This is an imitation of De
Valangin’s arsenical solution, called by the inventor, who was a practitioner in London,
solutio solventis mineralis. It was originally made by subliming three parts of arsenious acid
with eight of common salt, and dissolving the product in a determinate quantity of dilute
muriatic acid. The sublimation directed by De Valangin with common salt had no effect
on the arsenious acid; and, accordingly, his preparation may be considered to have been a solution of arsenious acid in muriatic acid, becoming terchloride of arsenic by the mutual decomposition of the acids. In the London formula thirty grains of arsenious acid are dissolved in twenty Imperial fluidounces of the menstruum, that being the measure to which the preparation is ultimately brought. Hence each fluidounce contains a quantity of terchloride, equivalent to a grain and a half of arsenious acid. Terchloride of arsenic is a colourless anhydrous liquid of the sp. gr. 2.18. It is strongly acid to litmus, completely soluble in alcohol and ether, and possesses the power of dissolving a considerable proportion of arsenious acid. (Dr. Penny and Mr. W. Wallace, Philos. Mag., xii. 365.)

**Medical Properties.** This arsenical solution has considerable reputation in London as an alternative. It is chiefly employed in the treatment of chorea and lepra vulgaris. Dr. Farre, of London, states, as the result of his observation, that it effectually cures the worst forms of chorea. (Pereira, Mat. Med., 3d ed., p. 670.) The late Dr. Pereira, who used this solution on numerous occasions, found it efficacious in the treatment of chorea and lepra, but was not convinced of its superiority to Fowler's solution. It is said to be less apt to disturb the stomach; but it must be recollected that De Valangin's solution is only three-eighths as strong as that of Fowler, and yet is not given in a larger dose. The average dose is five drops three times a day. Dr. Farre begins with three drops three times a day, increasing one drop each day, until the dose reaches ten drops three times a day. Whenever the stomach becomes disordered, the medicine should be suspended; and, when renewed, it must be given in the original dose. Dr. Fuller, of London, praises this solution as a remedy in rheumatic gout, if the urine be clear and of low sp. gr. In such cases he gives it in the large dose of from ten to twenty drops, either alone or combined with cinchona. If mineral acids are indicated, muriatic acid is added.

**CHLORIDE OF BROMINE. Brominii Chloridum.** This chloride is prepared by passing chlorine gas through bromine, and condensing the vapours which form by a freezing mixture. It is a reddish-yellow, very mobile and volatile liquid, emitting dark yellow fumes, which have a very powerful odour, and cause a flow of tears. Its taste is hot and unpleasant.

CHLORIDE OF MAGNESIUM. Magnesii Chloridum. Muriate of Magnesia. When a concentrated solution of this salt is evaporated to dryness, it is partially decomposed into magnesia and muriatic acid, the latter being evolved. By a careful evaporation, stopping it so soon as the vapour begins to reddish litmus paper, the chloride may be obtained in the state of a fused hydrate, having the composition MgCl₂.H₂O. (Casseea, Chem. Gaz., Oct. 15, 1853, p. 384.) The physiological action of this bitter and very deliquescent salt is the subject of a memoir by Dr. Lebert. He finds it to act mildly and favourably as a purgative, producing a flow of bile, and an increase of appetite. On account of its extreme deliquescence, he recommends it in the liquid form, prepared by dissolving the salt in its weight of water. Of this solution he gives an ounce sufficiently diluted to an adult, and half an ounce to a child from 10 to 14 years of age. (Arch. Gén., 4e sér., iii. 448.)

**CHLORIDE OF MERCURY AND QUINIA. Hydrargyri et Quiniae Chloridum.** This compound has been prepared by Mr. McDermott, of Dublin, by uniting chemically corrosive sublimate with quinia. The corrosive sublimate was found to be reduced to the state of calomel; and, hence, it may be inferred that half the chloramine of the former united with the quinia. This preparation has been found useful in the treatment of obstinate skin diseases, given in the dose of a grain two or three times a day.

**CHLORIDE OF POTASSA. SOLUTION OF. Liquor Potassae Chloratiae. Javelle's Water. Eau de Javelle.** This is prepared from carbonate of potassa precisely as the solution of chlorinated soda from carbonate of soda, and probably has an analogous composition. (See Liquor Sodae Chloratiae.) It is employed for taking out fruit stains, &c. from linen.

**CHLORIDE OF SILVER. Argenti Chloridum.** This has been already referred to as being inevitably formed when nitrate of silver is given internally. (See page 1011.) It is readily prepared by adding a solution of common salt to one of nitrate of silver, as long as it produces a precipitate. As first thrown down it is a white curdy substance, but it soon becomes discoloured when exposed to the light. It is decomposed by solutions of the caustic alkalis, which convert it into oxide, but not by their carbonates. After the formation of the oxide in this way, the addition of sugar reduces it, and revives the silver. (Levol.) Chloride of silver has been used, rubbed on the tongue, in syphilis, and internally in epilepsy, chronic dysentery and diarrhoea, and other diseases in which nitrate of silver has been given. The dose is from one to three grains or more, four or five times a day. Dr. Perry administered it at the Philadelphia Hospital, Blockley, in chronic dysentery, with the immediate effect of diminishing the number of stools. The crystallized ammonio-chloride of silver has been given in syphilitic affections, in the dose of the fourteenth of a grain. It is formed by saturating
solution of ammonia, by the aid of heat, with chloride of silver, and allowing the liquid to cool in a stopped bottle. It crystallizes in cubes, and is very liable to decomposition. B.

CHLORINATED ANÆSTHETIC COMPOUNDS. By the mutual action of chlorine and olefiant gas, an oily liquid is obtained, discovered by the associated Dutch chemists, and called Dutch liquid. The empirical formula of this compound is \( C_7H_3Cl_2 \), which makes it the dichloride of ethylene; the rational formula is \( C_7H_5Cl_2 \). When it is acted on by an alcoholic solution of potassa, muriatic acid is separated by the formation of chloride of potassium, and a compound represented by \( C_7H_4Cl \) is set free. By the action of additional chlorine, the Dutch liquid is susceptible of having each equivalent of hydrogen successively replaced by one of chlorine, forming four new compounds; namely, \( C_7H_3Cl_3 \), \( C_7H_2Cl_4 \), \( C_7HCl_5 \), \( C_7Cl_6 \). The last compound here is evidently a 6-4 chloride of carbon; and the others are called by Regnault, in allusion to the replacing chlorine, without noting the disappearing hydrogen, monochlorinated, dichlorinated, and trichlorinated Dutch liquid. The Dutch liquid has been tried as an anaesthetic by Prof. Simpson and Mr. Nunnely. Prof. Simpson was not satisfied with its effects; but Mr. Nunnely, having administered it frequently in practice, found it perfectly agreeable in every respect. Its use, he alleges, is not attended by the troublesome excitement produced by ether, or by the tendency to collapse caused by chloroform. Two forms of Dutch liquid have been recently experimented with by Dr. Aran, of Paris; and one of them furnished satisfactory clinical results. The liquid which gave favourable results has been ascertained by Mialhe and Flourens to be the monochlorinated Dutch liquid; but its cost proved to be too high to allow of its general use as a therapeutical agent. In consequence of this objection to the monochlorinated liquid, Mialhe and Flourens were induced to search for a substitute in the corresponding compound of a parallel series of ethers, formed by the action of chlorine on muriatic ether. When muriatic ether (\( C_7HCl \)) is acted on by successive portions of chlorine, the hydrogen is replaced by the latter, equivalent for equivalent, and there are formed the five following compounds: \( C_7HCl_2 \), \( C_7H_2Cl_3 \), \( C_7HCl_4 \), \( C_7Cl_5 \), \( C_7Cl_6 \). Of this series, the first member is isomeric with the Dutch liquid; the second, third, and fourth with the mono- and trichlorinated Dutch liquid, and the fifth is the 6-4 chloride of carbon, the terminating compound of the other series. The first member, though identical with the Dutch liquid in elementary composition, and having a vapour of the same density, has, nevertheless, a lower boiling point, and is different in chemical properties. Thus, it is not decomposed by an alcoholic solution of potassa, as the Dutch liquid is, and is not acted on by potassium, while the Dutch liquid is immediately attacked by it. These facts show that the atomic constitution of these two substances must be different. In like manner the second, third, and fourth members of this series are different in chemical properties from their isomeric representatives in the Dutch liquid series. In denoting the different degrees of chlorination of the muriatic ether series, Regnault indicates merely (as in the Dutch liquid series) the number of eqs. of chlorine supposed to replace hydrogen. Accordingly, he calls the first member of the series monochlorinated muriatic ether, corresponding to the Dutch liquid; and the second, third, and fourth, bi-, tri-, and quadrichlorinated muriatic ethers, corresponding to the mono- bis- and trichlorinated Dutch liquids. This confusion of nomenclature arises from the fact that the replacement by chlorine sets out from five eqs. of hydrogen in the muriatic ether series, and from four eqs. in the Dutch liquid series.

From the explanations above given, it will be understood that the compound of the muriatic ether series, corresponding to the monochlorinated Dutch liquid, is the bichlorinated muriatic ether. This compound proved too volatile to act advantageously as a local anaesthetic. The tri- and quadrichlorinated ethers are denser and less volatile, and acted more favourably. The conclusion arrived at by Mialhe and Flourens appears to be that the four chlorinated muriatic ethers all possess anaesthetic properties; and, as it would be difficult to separate them, they propose the use of the mixed ethers, consisting principally of the tri- and quadrichlorinated compounds, as an anaesthetic, under the indefinite name of chlorinated muriatic ether.

Chlorinated muriatic ether (chlorinated chlorohydric ether) is a colourless, very mobile, neter liquid, having an aromatic ethereal odour, and hot saccharine taste. It is sparingly soluble in water, but readily soluble in alcohol, ether, and most of the fixed and volatile oils. It is not inflammable, in which respect it agrees with chloroform. Being a mixture of different liquids, its sp. gr. is not uniform. Its boiling point varies from 230° to 260°. According to the experiments of Flourens, it has a similar action to chloroform, the most important of the chlorinated anaesthetics. (See Chloroformum.) Its local action is that of a powerful sedative. (B. Cucuel, Ann. de Thérap., 1853, 102.)

CHROME. Chromium. As it has been customary, in this work, to notice more or less fully the metals of which one or more compounds are official, even though the metal may not hold the same position, it is proper to give a brief notice in this place of the metal chrome, of which two compounds, chromic acid and bichromate of potassa, are contained in the Materia Medica Catalogue of our Pharmacopoeia. Chrome was discovered by Vaquelin in 1797. Its most common ore is the chromite of iron, consisting of protoxide of iron and
sесsюiоiоide of chrome. This is not an abundant mineral; and one of the most copious sources of it is in the chrome mines of south-eastern Pennsylvania. Chrome is obtained by igniting its oxide intensely in contact with charcoal. It is a silvery-white metal, of a glassy-white colour like platinum, with some luster, and is very hard, so that it scratches glass, and ground up with water forms a beautiful blue pigment. It does not change by exposure to the air, and is with difficulty attacked by the acids. It forms with oxygen five compounds: 1. the protoxide (CrO), 2. the sesquioxide (Cr₂O₃), 3. chromic acid (Cr₂O₃). Of the two others, one may be considered as a compound of the protoxide and sesquioxide (CrO₃Cr₂O₃), and the other, called perchromic acid, is said to consist of two eqs. of chrome and seven of oxygen (CrO₇). Chrome combines with chlorine in two proportions, forming the protochloride and sesquichloride. The chief value of chrome in the arts is as the source of bichromate of potassa, extensively used in dyeing and valuable for the facility with which it parts with oxygen, and as the base of certain beautiful pigments.

W. CHROME YELLOW. This is the neutral chromate of lead, prepared by precipitating a solution of the nitrate of lead with chromate of potassa. It is of a beautiful lemon-yellow colour. The subchromate of lead, consisting of one eq. of acid and two eqs. of base, is of a red colour, and is sometimes used as a pigment. Chrome green is a mixture of chrome yellow and Prussian blue.

W. CICHIORIUM INTYBUS. Chicory. Succory. A perennial herbaceous plant, indigenous in Europe, but naturalized in this country, where it grows in fields, and in roads along the fences, in neighbourhoods which have been long settled. It is one or two feet high, with large, compound, beautifully blue flowers, which appear in July and August, and serve to distinguish the plant at first sight. The whole plant has a bitter taste, without acrimony, or any very peculiar flavour. The taste is strongest in the root, and weakest in the flowers. The leaves, when young and tender, are said to be sometimes eaten as salad in Europe. Succory is gently tonic without being irritating, and is considered by some authors as aperient and deobstruent. It is said to be useful, if freely taken, in hepatic congestion, jaundice, and other visceral obstructions in the early stages; and is affirmed to have done good even in pulmonary consumption. The usual form of administration is that of decoction, which is prepared by boiling one or two ounces of the root, or a handful of the herb, in a pint of water. The root, dried and roasted, is much used in certain parts of Europe as a substitute for coffee, and is said also to be mixed fraudulently with ground coffee for sale. In preparing it for coffee, Dausse recommends that the dried root should be cut into rather large and equal pieces, which are to be roasted until they lose 140 out of 500 parts. The pieces are then easily ground in a mill, and afford a yellowish-brown powder. (Pharm. Cent. Blatt, Oct. 1850, p. 688.) The plant is now largely cultivated both in England and on the Continent, to supply the demand for its root, which has grown out of its use for admixture with coffee, or as a substitute. In France alone the annual consumption is said to be 16 millions of pounds. (Pharm. Journ., Aug. 1850, p. 125.) The garden endive is a species of Ciciorium, denominated C. Endivia.

W. CICUTA VIROSA. Water Hemlock. Cowbane. A perennial, umbelliferous European plant, growing on the borders of pools and streams. It is very poisonous, proving fatal to most animals which feed upon it, though said to be eaten with impunity by goats and sheep. Several instances are on record of children who have died from eating the root by mistake for parsnip. It operates as an acrid narcotic, producing inflammation of the stomach, together with symptoms which indicate cerebral disturbance, such as vertigo, intoxication, and convulsions. Infusion of galls is recommended as an antidote, but should not be relied on to the exclusion of emetics. When the plant vomits, as it frequently does, fatal effects are less apt to ensue. It is said to be less poisonous dried than fresh; and it has been inferred that the active principle is volatile. But the volatile oil, obtained by distillation, was found by Simon, of Berlin, not to be poisonous. Indeed, from the experiments of M. Julius Trapp, of St. Petersburg, it appears to be identical with the volatile oil of cummin seeds (Cumminum Cuminum), which rank among the aromatics. (Chem. Central Blatt, June 9, 1858, p. 414.) On the other hand, the alcoholic extract of the dried root operated as a violent poison upon animals. (Annal. der Pharm., xxxi. 258.) At present the plant is never used internally, having been superseded by Conium maculatum. Externally it is sometimes employed as an anodyne poultice in local pains, particularly those of a rheumatic or gouty nature.

Cicuta maculata or American water hemlock, which grows in meadows and on the borders of streams throughout the United States, is closely analogous, in botanical character and in effects, to the European species. In several instances, children have been fatally poisoned by eating its root. This consists of several oblong, fleshy tubers, sometimes as long as the finger, spreading out from the base of the stem, and having a smell and taste not unlike those of parsnip. Until recently it has not been used in medicine; but we are told in Mr. Stearns' account of the medical plants of Michigan, that Dr. Norton, of Minnesota, highly recommends it as a specific in nervous and sick headache. (Proceed. of Am. Pharm. Assoc.,
For a full account of the plant, see Bigelow's Medical Botany (i. 125). The seeds have been analyzed by Mr. J. E. Young, who found in them albumen, tannic acid, gum, fixed oil, resin, volatile oil, chlorophyll, colouring matter, a peculiar acid, and an organic alkaloid supposed to be identical with conia. (Am. Journ. of Pharm., xxvii. 204.)

In cases of poisoning by either of these species of Citaca, vomiting should be induced as speedily as possible, and maintained till the stomach is thoroughly evacuated, after which the system must be supported.

CITRATE OF IRON AND MAGNESIA. Ferri et Magnesia Citrata. This double salt has been introduced to the notice of the profession by M. Van der Corput. It is made by dissolving two ounces of freshly precipitated hydrated oxide of iron in a moderately heated solution of three ounces of citric acid, and saturating the liquor with carbonate of magnesia. The solution, after filtration, is evaporated by means of a water-bath to a syrupy consistency, and spread on glass to dry in scales. The quantity of carbonate required is nearly an ounce. Three and a quarter ounces of sulphate of iron will furnish by decomposition the necessary hydrated oxide for three ounces of the acid. (See formula for *Ferri Oxidum Hydratum.*) This salt is in transparent, greenish-yellow scales, having a slightly ferruginous, somewhat acid taste. It is very soluble in water, but insoluble in alcohol and ether. It may be given in doses of from five to ten grains, in the form of solution, syrup, or pill. See the remarks of Prof. Procter on this preparation, contained in the American Journal of Pharmacy (Oct. 1850, p. 315).

CITRATE OF SODA. Soda Citrata. This salt may be formed by saturating a solution of citric acid with bicarbonate of soda, evaporating the liquid, and setting it aside to crystallize. It is a white salt, crystallized in six-sided pyramids, and having a saline taste without any bitterness. Citrate of soda has been proposed by M. Guichon, of Lyons, as a pleasant purgative, having properties similar to those of citrate of magnesia, and, though possessing a taste more decidedly saline than the latter, having the advantages of cheapness, and of a constant solubility, which permits it to be associated with other medicinal preparations. The dose is from ten to fourteen drachms, given in simple aqueous solution, or acidulated with citric acid and sweetened.

CIVET. Zibethum. This is an odorous substance, obtained from two animals of the genus Viverræ; *V. Cicetta* or civet cat of Africa, and the *V. Zibetha*, which inhabits the East Indies. It is secreted into a cavity opening between the anus and external genitals, and is collected from animals confined for the purpose. It is semi-liquid, unctuous, yellowish, becoming brown and thicker by exposure to the air, of a very strong, peculiar odour, similar to that of musk, though less agreeable and less diffusible, and of a bitterish, subacrid, disagreeable fatty taste. When heated it becomes quite fluid, and at a higher temperature takes fire, and burns with a clear flame, leaving little residue. It is insoluble in water, and only slightly soluble in ether and cold alcohol; but heated alcohol dissolves it almost entirely, depositing it again upon cooling. It contains, among other ingredients, a volatile oil, fat, and free ammonia. In medicine it was formerly employed as a stimulant and anti-spasmodic, like castor and musk; but it is now used exclusively as a perfume.

CLEMATIS ERECTA. *Upright Virgin's Bower.* A perennial European plant. The leaves and flowers have an acid, burning taste. When bruised in a mortar they irritate the eyes and throat, giving rise to a flow of tears and to coughing; and applied to the skin they produce inflammation and vesication. Hence the name of *flammula Jovis*, by which the plant was known in older pharmacy. The acrimony is greatly diminished by drying. Störrck found this species of Clematis useful in secondary syphilis, cancerous and other foul ulcers, and severe headaches. He gave it internally, and at the same time applied the powdered leaves to the surface of the sore. It acted as a diuretic and diaphoretic. Two or three drachms of the leaves were infused in a pint of water, of which he administered four ounces three times a day. He also employed an extract, in the dose of a grain or two in the course of a day. At present the plant is not used.

Other species of Clematis have the same acrid properties. Among these are *C. Flammula* or *sweet-scented virgin's bower*, which, though a native of Europe, is cultivated in our gardens, *C. Vitalba* or *traveller's joy*, also a native of Europe, and several indigenous species, of which *C. Virginica* or *common virgin's bower*, *C. Viorna* or *leather flower*, and *C. crispus* have been particularly cited by authors as proper substitutes for the *C. erecta* used by Störrck. All these are climbing plants. *C. Vitalba* has been used in Europe with success in the cure of itch. For this purpose the roots and stems, bruised, and boiled for a short time to diminish their acrimony, were infused in boiling oil, which, thus impregnated, was applied to the skin several times a day. Twelve or fifteen applications were usually sufficient.

COAL TAR. When bituminous coal is subjected to dry distillation, besides the indescribable gases which serve for lighting, and the charcoal left behind as coke, which is a valuable fuel, there are formed, through the reactions between the disengaged principles of the coal, numerous other products, necessarily more or less varying in character and amount, not only according to the kind of coal used, but also with the varying circumstances of the
decomposition process. Most of these newly-formed bodies, all of which are volatile, are condensed into a dark thick liquid or semi-liquid called coal tar. Formerly this was considered as refuse matter, and the most embarrassing problem for the manufacturer was how to get rid of it most conveniently. But science and industry have combined to wrest from this seemingly useless mass many substances of great value in the arts, and several which have entered into the catalogue of remedies. In an excellent paper by M. E. Kopp, an abridgment of which is published in the American Journal of Pharmacy (1861, Jan., p. 39, March, p. 129, and May, p. 245), a general view is given of the constituents of coal tar, to which we wish to acknowledge our indebtedness for most of the statements which follow.

Our purpose is to give a condensed view of these substances, and, when found of importance in their therapeutic relations, to treat of them more fully, should they not have been already commented on under distinct heads. When coal tar is submitted to distillation and rectification, it yields the following products in variable proportion. They may be arranged in the three divisions of solids, liquids, and gases.

1. Solids. Carbon, naphthalin, paranaphthalin or anthracein, paraffin, chrysene, and pyrene.

2. Liquids. These may be subdivided into acid, neutral, and basic substances. The acids are rosolic, brunolic, carbohydrogen, and butyric. The neutral bodies are water, essence of tar, light oil of tar, heavy oil of tar, benzole, toluole, camole, cymole, propyl, butyl, amyl, caproil, hexylene, and heptylene. The bases are ammonia, methyllum, ethylamin, anilin, quinolin, picolin, toluidin, lutudin, cumidin, pyrrhol, and phetin.

Of the above substances a considerable number have not yet been individually applied to any important practical purpose. Some are so well known to the reader as to require no further notice. The remainder we shall endeavour to consider more or less fully as their novelty and importance may seem to demand.

Before submitting the tar to distillation, it is to be freed as far as possible from the ammonia it may contain, which is mixed up with the mass in impure watery solution, chiefly probably as the carbonate. For this purpose it is heated to a point between 170° and 212° F., by which it is rendered more liquid, so that the water holding the ammonia in solution can be drawn off. This impure ammoniacal liquid is afterwards treated with sulphuric acid, by which the sulphate of ammonia is obtained, and this, by sublimation with chloride of sodium, yields muriate of ammonia; and from this source almost exclusively the market is at present supplied with the different ammoniacal compounds.

Having been thus freed from ammonia, the tar is next distilled at a relatively low temperature, which is most conveniently regulated by means of steam. The object is to obtain the lighter liquids, of which the boiling point is comparatively low. The heat employed should not exceed 390° F.; and, when the sp. gr. of the condensed products reaches 0.850, the process is suspended. The product of this first distillation is very complex, containing, among other substances, three carbohydrogens of special interest to the physician; viz., dihydrocarbolic acid (C_{14}H_{10}), which has already been treated of, amyl (C_{14}H_{28}), the radical of fusel oil or amylic alcohol, also before considered, and propyl (C_{6}H_{13}), the radical of the alkaloid propylamnia, of which we propose to treat in the following pages. This lighter oil is known as light oil of tar or coal naphtha. It is purified by first agitating it with 5 per cent. of concentrated sulphuric acid, allowing it to rest for a day or two in order that the acid and impurities may subside, then washing it with water, and afterward with 2 per cent. of a solution of caustic soda of the sp. gr. 1.382, to separate adhering acid, and finally distilling with a current of steam. Thus purified, it has the sp. gr. 0.815 to 0.820, and is not frequently sold under the name of benzine, which it would be well to restrict to this product, reserving the name of benzole for the pure carbohydrogen. Benzine is used for various purposes in the arts, generally connected with its great solvent power.

When the distillation of the tar is suspended, the steam is withdrawn, and the heat being increased to between 390° and 410° F., the distillation recommences; and the mixed oils that now come over and condense have a sp. gr. from 0.880 to 0.885, instead of 0.850, the sp. gr. of the lighter oil. This heavier product is distinguished by the name of the heavy oil of tar. It contains the acids and organic bases already enumerated, from which it is freed by treatment with sulphuric acid and one of the fixed alkalies and redistillation, in the same manner as above described for the light oil, using 10 per cent. of sulphuric acid instead of 5, and 6 per cent. of solution of soda instead of 2. The heavy oil thus purified is used as lamp oil, and is very largely consumed. Before distillation this oil has a disagreeable sulphurous odour, owing to the decomposition of the sulphuric acid used in purifying it, from which it is freed by shaking it with solution of sulphate of iron before distillation, or, after distillation, with addition of caustic soda to the sulphate. A blackish deposit of sulphuret of iron takes place, and the oil loses its odour. (Kopp.)

The solid or semi-solid mass, which forms out of the last products of the distillation upon cooling, is also complex; but consists largely of the two concrete bodies, naphthalin and par
affin, the proportion of each of which to the other varies according to the kind of coal used, and to the degree of heat employed. According to Mr. Joseph Taylor, the product of naphthalin is very great when the coal has been decomposed at a high temperature. He states that it is easily obtained from the latter portions of the light oil, which, if collected separately and set aside, become semi-solid on cooling. This concrete mass is pressed to separate the liquid portion, and may be purified by crystallization from naphtha or sublimation. Paraffin, according to the same authority, exists in small quantity in coal tar, being destroyed by the high temperature necessary in decomposing the coal in the manufacture of gas. (Pharm. Journ., Jan. 1861, p. 364.) M. Kopp, on the contrary, states that the tar from Boghead coals is rich in paraffin. (Am. Journ. of Pharm., Jan. 1861, p. 41.) When the last products of distillation cool, this separates as a buttery mass, while naphthalin, under similar circumstances, assumes a crystalline character. The paraffin and the heavy oil which drains from it, and which is called paraffin oil, are purified in the same manner as the lighter and heavier oils above referred to by sulphuric acid, which, however, is sometimes aided by oxidizing agents such as bichromate of potassa, peroxide of manganese, or hypermanganate of potassa, and subsequent washing with solution of caustic soda. After this the paraffin is either redistilled, or purified by a second treatment with sulphuric acid and washing. It is now mixed with 1 per cent. of stearic acid, which, on the addition of the caustic soda, forms a soap which, when the paraffin is melted, envelopes the impurities, and separates in floculei, leaving the paraffin pure. Paraffin having been already described under the head of Creasotum, in Part I. (page 281), requires no further consideration here; and naphthalin will be considered in its proper alphabetical position in the present part of this work.

The acid and alkaline washings resulting from the purifying processes to which the oils have been subjected contain all the acids and alkaloids already mentioned as among the products of the distillation of coal tar. It has become important to obtain these separate, as some of them have recently acquired great value in the arts as the source of colouring substances used in dyeing, and others are employed as medicines. M. Kopp proposes the following method of obtaining them. Collect separately the acid and the alkaline liquors, determine how much of the latter would suffice to neutralize a given portion of the former, then mix the alkaline solution with twice the quantity of acid sufficient to saturate it. If the mixture be quickly made a heat will be generated near to the boiling point; and a concentrated solution of bisulphate of soda will be formed, holding in solution the bisulphates of the organic alkaloids, while the carbolic acid and creasote will separate in the form of a brown oil. If this be removed and distilled, a light neutral oil will first pass, and then the creasote and carbolic acid nearly pure; and it is probably this mixture or some one like it that is now improperly sold in the market under the name of creasote. The acid solution, being now allowed to cool, deposits bisulphate of soda in crystals. The portion of acid solution, not used to saturate the alkaline, may now be added, the mixture heated to 150° or 180°, chalk or lime added short of complete saturation, and the liquid concentrated. After the deposit of sulphate of lime has been separated, the concentrated solution of the acid sulphates is to be mixed with an excess of quicklime, and distilled from an iron retort. Sulphate of lime is left behind, and the liberated alkaloids pass over and condense with water. If the water be sufficient to hold them in solution, muriatic acid is to be added to saturation, and the liquid evaporated, first over the naked fire, but towards the close upon a water-bath, nearly to dryness. The muriates thus formed are mixed with an excess of lime and distilled, and an oily liquid is thus obtained, consisting chiefly of the alkaloids, anilin (anilina), quinolin (quinolina), and toluidin (toluidina), sufficiently pure to be used in preparing the various colouring substances, which constitute all their value in the arts. Of the different products resulting from the above process, all that are used in medicine, namely creasote, carbolic acid, and anilin, have been treated of under distinct heads in this work; to which the reader is referred. (See Creasotum in Part I, and Anilin and Carbolic Acid, in their proper alphabetical positions in Part III.)

This is not the place to treat of the methods in which the several beautiful and magnificent colours are prepared from anilin and the other coal-tar alkaloids; as the subject belongs exclusively to the arts. It will be sufficient to refer to the fine anilin violet, produced by reaction with bichromate of potassa; the magnificent purple called fuchsin or magenta, resulting from the reaction between anilin and chloride of tin; and the splendid anilin red obtained by treating the same alkaloid with bichloride of mercury or perchloride of tin. Yellows, greens, and various other tints are prepared either with anilin or the other coal-tar alkaloids, which appear to share its wonderful colouring powers.

The residue of coal tar left after its distillation, commonly called pitch, has also been applied to various useful purposes; being mixed with coal dust or small fragments of coal, otherwise useless, to fit them for fuel; or used as a paint to wood in order to preserve it; or employed in the preparation of what are called asphaltum pavements and for covering roofs. (Taylor.)

Coal tar itself has been ascertained to answer admirably well, in certain instances, the purposes of a disinfectant. MM. Corne and Demeaux prepared a mixture of coal tar and
plaster of Paris, in the proportion of from one to three parts of the former to one hundred of the latter, which, having been submitted for trial to a committee of the Academy of Sciences of Paris, was reported on favourably by the committee, of which M. Velpeau was at the head. The mixture should be made of the best modelling plaster, and should have a gray colour after the ingredients have been well rubbed together. It is in the form of powder, and may be applied on lint, or mixed with cataplasms, or sprinkled thickly on ulcerated surfaces. It is applicable to fetid, sloughing, or gangrenous ulcers, to offensive suppurating surfaces, sanious wounds, &c., and may be used also to correct disagreeable odours, in autopsies, about the beds of dirty patients, and wherever there are fetid discharges. (Journ. de Pharm., Oct. 1859, p. 296.)

COBALT BLUE. This beautiful pigment is a compound of oxide of cobalt and alumina, obtained by precipitating the mixed solutions of a salt of alumina and of cobalt by means of an alkali, and washing, drying, and strongly calcining the precipitate. (Berzelius.) The cobalt blue of Thenard is made by heating together the hydrated subphosphate of cobalt and hydrate of alumina. It is used in painting. An oxide of cobalt, prepared by precipitating the chloride with potassa, has been employed in rheumatism. It is emetic in the dose of 10 or 20 grains. The salts of the metal are irritant poisons.

COBWEB. Spider's Web. Tela Aranea. The genus Aranea of Linn. has been divided by subsequent naturalists into several genera, of which the Tegenaria of Walkenaer is the one that includes the medicinal species of spider. The T. domestica of Europe, and T. medicinalis of this country (Henz, Journ. Acad. of Nat. Sci., ii. 53), are the particular species which have attracted most attention. They inhabit cellars, barns, and other dark places, and are of a brown or blackish colour. It is affirmed that the web of the field spider is inefficacious, while that collected in the cellars of houses, &c. has extraordinary medical virtues. Several authors speak in very decided terms of its powers as a febrifuge and antispasmodic. According to Dr. Robert Jackson, it is superior even to bark and arsenic in the cure of intermittents, and is, moreover, highly useful in various spasmodic and nervous diseases, controlling and tranquillizing irregular nervous action, exhilarating the spirits, and disposing to sleep, without producing any of the narcotic effects of opium on the brain. Among the complaints in which it has been found useful, besides intermittent fever, are periodical headache, hectic fever, asthma, hysteria, and nervous irritations attended with morbid vigilance and irregular muscular action. It will be observed that these are, for the most part, affections over which the imagination has much control. The dose of spider's web is five or six grains, to be given in the form of pill, and repeated every three or four hours. Dr. Jackson states that its influence is not in proportion to the quantity administered, and that he obtained the same effects from ten as from twenty grains. This might well be, if the supposition be allowed that its chief operation is through the imagination. Spider's web has also been used, with asserted advantage, as a styptic in wounds, and a healing application to superficial ulcers. Spiders themselves were formerly employed in the treatment of intermittent fever, and this application of the web is not of recent origin.

COCHLEARIA OFFICINALIS. Common Scurvy-grass. This is an annual or biennial plant, sending up early in the spring a tuft of radical leaves, which are heart-shaped, roundish, of a deep shining-green colour, and supported on long footstalks. The leaves of the stem are alternate, oblong, somewhat sinuate, the lower petiolate, the upper sessile. The stem is erect, branched, angular, six or eight inches high, and bears, at the extremity of the branches, numerous white cruciform peduncled flowers, in thick clusters. The fruit is a roundish two-celled pod, containing numerous seeds. The whole plant is smooth and succulent. It is a native of the northern countries of Europe, where, as well as in the United States, it is occasionally cultivated in gardens. The whole herb is officinal. It has, when fresh, a pungent, unpleasant odour if bruised, and a warm, acrid, bitter taste. These properties are lost by drying. They are imparted to water and alcohol by maceration, are retained by the expressed juice, and probably depend on a peculiar volatile oil, which is separable in very small quantity by distillation with water. Dr. Geiselser has shown that, when the dried herb is mixed with water and a little myrosin (see Sinapis), the taste and smell of the fresh plant are developed; proving that, as in black mustard, the volatile oil is produced by reaction between a fixed principle in the plant and water, under the influence of myrosin acting as a ferment. (Chem. Cent. Blatt, Feb. 20, 1856, p. 124.) The oil was at one time supposed to be identical with the oil of mustard, but M. Geiselser has shown it to have a different composition; its formula being C\textsubscript{11}H\textsubscript{19}O\textsubscript{3}S, which is oil of garlic plus one eq. of oxygen. (See Am. Journ. of Pharm., Sept. 1859, p. 416.)

Common scurvy-grass is genteel stimulant, aperient, and diuretic. It is highly celebrated as a remedy in sea-scurvy, and has been recommended in chronic obstructions of the vessels, and certain forms of chronic rheumatism. The fresh plant may be eaten as a salad, or used in the form of infusion in water or wine, or of the expressed juice. Alcohol and water are impregnated with its virtues by distillation; and the distilled spirit has been
found useful in paralysis, in the dose of thirty drops several times a day. The expressed juice may be used as a local application in scurvy affections of the gums. W.

**COCO-NUT OIL.** *Coco-nut Oil. Coco-nut Butter.* This must not be confounded with the fixed oil of the chocolate nut, which is often called coca butter, and which has been described in Part I. (page 604). The substance here considered is the fixed oil of the coco-nut, which is the fruit of a species of palm, denominated botanically *Cocos nuefera,* and universally known by the name of coco-nut tree, or, as it is frequently spelled, cocoanut tree. The oil is obtained either by expression or decoction. It is of a fine white colour, of the consistence of lard at ordinary temperatures, becoming solid like suet between 40° and 50°, and liquid at about 80°, of a bland taste, and a peculiar, not disagreeable odour. It is readily dissolved by alcohol. According to Brandes, it consists mainly of a peculiar fatty principle called cocin, which yields cocin acid by saponification. (Journ. de Pharm., xxiv. 652.) It has since been found to contain several solid and volatile acids, as caproic, caprylic, capric, and pichuric acids. (Ibid., 3e sér., xv. 69.)

This oil has been used for various purposes in medicine and pharmacy. Dr. Theophilus Thomson has found it to possess virtues similar to those of cod-liver oil, and has used it with advantage in consumption. In some instances it appeared to arrest the progress of phthisis as decisively as that oil, over which it has the advantages of being cheaper, more palatable, and less apt to produce nausea. (Clin. Lect. on Pulmonary Consumption, Am. ed., p. 128.) Dr. J. H. Warren of Boston, gives similar testimony in its favour. (Jottings and Surg. Journ., iii. 377.) In Germany it has been used in pharmacy, to a considerable extent, as a substitute for lard, to which, according to Pettenkofer, it is preferable on account of its less tendency to rancidity, its more ready absorption when rubbed on the surface of the body, and its less liability to produce chemical changes in the substances with which it is associated. Thus, the ointment of iodide of potassium, when made with lard, becomes yellow in a few days; while, if made with coco-nut oil, it remains unchanged for two months or more. Vegetable substances also keep better in ointment prepared with this oil than with lard. Besides, it takes up one-third more water, which is a useful quality, when it is desirable to apply saline solutions externally. To prepare it for use, nothing more is ordinarily necessary than to melt it at a moderate heat, and strain it through linen. If coloured, it may be digested with powdered animal charcoal, and subsequently filtered through paper. (Am. Journ. of Pharm., xxix. 331, from Buchner’s Repertorium, 1856, 485–8.) Coco-nut oil has been used in the manufacture of soap; but we are told that the soap acquires a very offensive odour when long kept. A preparation has been shown to us, said to be the liquid part of coco-nut oil, prepared in London, and, under the name of coco-olein, used, instead of the oil itself, as a substitute for cod-liver oil. The dose of this, as well as of the oil, is half a fluidounce three times a day. If the oil is used, it may be readily brought to the liquid state by a gentle heat.

**CIELOCLINE POLYCARPA** (Alphonse De Candolle). *Unona polyacarpa* (De Cand.). *Berberin Tree. Yellow-dye Tree of Soudan.* This is a small tree, growing in Soudan, Sierra Leone, and other parts of Western Africa, the bark of which has recently come into notice, through the researches of Dr. Wm. F. Daniell, who has described both the tree and its bark in a paper, published in the Pharmaceutical Journal for Feb. 1857 (p. 389). When wounded the tree exudes a juice which produces a yellow stain upon linen, that cannot be washed out. The epidermis of the bark is greenish-gray, interrupted by occasional blackish patches; the inner layers are of a golden yellow, and very fibrous, so that they can be separated in riband-like bands. The bark is moderately but disagreeably bitter, and stains the saliva yellow. Water extracts its colour and bitterness. Dr. Stenhouse has ascertained that it contains berberina, found also in columbo, and in Berberis vulgaris. The bark is much used in Africa for dyeing yellow. In Sierra Leone it is employed topically, with assured advantage, in the treatment of obstinate ulcers, being applied both in the state of powder and in decoction.

**COLLINSONIA CANADENSIS.** *Horse-weed. Horse-balm. Richweed. Heal-all. Stone-root. Knot-root.* An indigenous plant, with a perennial, knotty root, and an herbaceous simple stem, about two feet high, furnished with two or three pairs of broad cordate-ovate, smooth leaves, and terminating in a pannicle of yellow flowers in branched racemes. The flowers are diandrous and monogynous, with a labiate calyx and corolla, the latter of which has the lower lip fringed. The plant grows in woods from Canada to the Carolinas, and flowers from July to September. The whole plant has a strong disagreeable odour, and a warm pungent taste. It is considered tonic, astringent, diaphoretic, and diuretic; and the root, in substance, is said to irritate the stomach, and produce vomiting, even in small doses. The plant is used in numerous complaints in domestic practice. It is preferred in the fresh state, as the active principle is volatile. A decoction of the fresh root is said to have been used with advantage in catarrh of the bladder, leucorrhoea, gravel, dropsy, and other complaints; and the leaves are applied by the country people, in the form of cataplasm or fomentation, to wounds, bruises, and sores, and in cases of internal abdominal pains.
COLUTEA ARBORESCENS. Bladder Senna. A shrub growing spontaneously in the southern and eastern parts of Europe, and cultivated in gardens as an ornamental plant. Its leaves are pinnate, consisting of from three to five pairs of leaflets, with an odd one at the end. The leaflets are obvate, slightly emarginate, smooth, and of a deep-green colour on the upper surface, grayish-green and somewhat pubescent beneath. The flowers are yellow, and the fruit vesicular, whence the plant derived its vulgar name. The leaflets are pungutive, and, in some parts of Europe, are used as a substitute for senna, which is said to be sometimes adulterated with them. Bladder senna is comparatively very feeble. It is administered in infusion or decoction, of which the dose is about half a pint, containing the virtues of from one to three ounces of the leaves.

COMPTONIA ASPLENIIFORMIA. Sweet Fern. A shrubby, indigenous plant, named from the resemblance of its leaves to the spleenwort fern, and belonging to the Linnean class and order Monocotyledones. It grows in thin sandy or stony woods, from New England to Virginia. All parts of it possess a resinous spicy odour, which is increased when the plant is rubbed. It is said to be tonic and astringent, and to be occasionally used in domestic practice as a remedy in diarrhoea, and various other complaints. It is employed in the form of decoction.

CONTRAYERVA. Contrayerva. This is the root of Dorstenia Contrayerva, and formerly held a place in the secondary catalogue of the U. S. Pharmacopoeia, but was dismissed at the late revision, and has now ceased to be official. The plant belongs to Tetrandria Monogynia of the Linnean system, and to the natural order Urticaceae. The following is its generic character:—"Receptacle common, one-leafed, fleshy, in which solitary seeds are nestled." (Willd.) This plant has a perennial, fusiiform, branching, rough, compact root or rhizoma, which sends up several leaves of an irregular shape, about four inches in length, lobed, serrated, pointed, and placed upon long radical footstalks, which are winged towards the leaves. The scapes or flower-stems are also radical, rise several inches in height, and support irregular quadrangular receptacles, which contain male and female flowers, the former having two stamens, the latter a single style. The capsule, when ripe, possesses an elastic power, by which the seeds are thrown out with considerable force. The plant grows in Mexico, the West Indies, and Peru. The root (rhizoma) is the official portion. According to Pereira, however, the contrayerva of the shops is the product of D. Brasiliensis, and is brought from Brazil. The term contrayerva, in the language of the Spanish Americans, signifies counterpoison or antidote, and was applied to this root under the impression that it had the property of counteracting all kinds of poison. The probability is that the root sold as contrayerva is derived from several species of Dorstenia, among which, besides D. Contrayerva, two others are mentioned by Dr. Houston, D. Houstonia and D. Drokena, the former growing near Campeachy, the latter near Vera Cruz. It is referred by Dr. Martius also to D. Brasiliensis, growing in Jamiaca, Trinidad, and Brazil. D. Contrayerva was the only one recognised in the Pharmacopoeia.

Properties. The root, as found in our shops, is oblong, an inch or two in length, of varying thickness, very hard, rough, and solid, of a reddish-brown colour externally, and pale within; and has numerous long, slender, yellowish fibres attached to its inferior part. The odour is aromatic; the taste warm, slightly bitterish, and pungent. The fibres have less taste and smell than the tuberous portion. The sensible properties are extracted by alcohol and boiling water. The decoction is highly mucilaginous. The tincture reddens infusion of litmus, and lets fall a precipitate on the addition of water. The root has not yet been analyzed, but contains starch and a volatile oil. Contrayerva is a stimulant tonic and diuretic, and has been given in low states of fever, malignant eruptive diseases, some forms of dysentery and diarrhoea, and other diseases requiring gentle stimulation. It is very seldom used in this country. The dose of the powdered root is about half a drachm.

CONVALLARIA MAJALIS. Lily of the Valley. This charming little garden flower is a native of Europe, and is found growing wild in the United States, upon the highest mountains of Virginia and Carolina. The flowers have a strong, delightful odour, which is in a great measure lost by drying. Their taste is nauseous, bitter, and acid. G. F. Waiz has found in the herb and root two peculiar principles, one crystalline and acid, which he calls convallarin, the other amorphous and bitter, and named convallamarin. For the mode of preparing them the reader is referred to the Am. Journ. of Pharm. (Nov. 1859, p. 577). Convallarin is in colourless rectangular wafers, scarcely soluble in water, but sufficiently so to render the solution acid, and to cause it when boiled to foam like soap and water. It is easily dissolved by alcohol. Its composition is represented by the formula C_{15}H_{14}O_{6}. It is a glucoside. Convallamarin is a white powder, very bitter and afterwards sweetish, soluble in water and alcohol, but not in ether. This also is a glucoside. Its composition is C_{10}H_{16}O_{8}. Taken internally the flowers are said to be emetic and cathartic, and their extract purges actively in the dose of half a drachm. They were formerly used in epilepsy and against worms. At present they are employed only as a sternutatory, for which purpose they are dried and reduced to a coarse powder. The root, which is also bitter, has
similar purgative properties, and, reduced to powder, is said to be sternutatory. From the analysis of Mr. Walz, it is probable that the virtues reside in the whole plant, and that it combines emetic and cathartic with tonic properties.

**Convallaria Polygonatum.** Linn. *Polygonatum uniforum.* Desfontaines.—*Solomon's Seal.* A perennial, herbaceous, European plant, the root of which is horizontal, jointed, white, and marked, at short intervals, with small circular impressions, which bear a remote resemblance to those made by a seal, and have served to give a name to the plant. The root is inodorous, and of a sweetish mucilaginous taste, followed by a slight degree of bitterness and astringency. It is said to be emetic. In former times it was used externally in bruises, especially those about the eyes, in tumours, wounds, and cutaneous eruptions, and was highly esteemed as a cosmetic. At present it is not employed, though recommended by Hermann as a good remedy in gout and rheumatism. The berries and flowers are said to be acrid and poisonous. *C. multiflora (Polygonatum multiforum, Desf.)*, which grows both in this country and Europe, is analogous to the preceding in properties. Dr. John H. Rauch found two fluidounces of a decoction, made by boiling two ounces of the root in a pint of milk, to produce nausea, a cathartic effect, and either diaphoresis or diuresis. He used it advantageously as an internal remedy in piles, and externally in the form of decoction, in the affection of the skin resulting from the poisonous exhalations of certain plants. *(Inaugural Essay, March, 1849.)*

**Convolvulus Panduratus. Wild Potato.** Under this name, the root of *Convolvulus panduratus* was formerly recognised in the secondary list of the U.S. Pharmacopoeia, from which, however, it was dismissed at the recent revision. The wild potato plant (for a figure of which see Barton's Med. Bot. i. 249) has a perennial root, and a round, purplish, procumbent or climbing stem, which twines around neighbouring objects, and grows sometimes twelve feet in length. The leaves, which stand alternately on long petioles, are broad, heart-shaped at the base, entire, or lobed on the sides like a guitar or violin, somewhat acuminate, deep-green on the upper surface, and paler beneath. The flowers are in fascicles, upon long axillary peduncles. The calyx is smooth and amentiform; the corolla, tubular, campanulate, very large, white at the border, but purplish-red at the base. The plant is indigenous, growing through the United States in sandy fields and along fences, and flowering from June to August. A variety with double flowers is cultivated in the gardens for the sake of ornament. The root, which was the official part, is very large, two or three feet in length, about three inches thick, branched at the bottom, externally of a brownish-yellow colour, and full of longitudinal fissures, internally whitish and milky, and of a somewhat acrid taste. The wild potato is feebly cathartic, and has been proposed as a substitute for jalap, but is scarcely used. It is thought also to be diuretic, and has been employed, with supposed advantage, in strangury and calculous complaints. Dr. G. M. Maclean considers it one of the best diuretics he has used, when given in infusion. *(N. Y. Journ. of Med., x. 375.)* Forty grains of the dried root are said to purge gently.

**Copal.** A resinous substance, brought from the East Indies, South America, and the western coast of Africa, but most abundantly from the first mentioned source. It is the concrete juice of different trees, and is furnished by exudation. The East India copal has been ascribed by some writers to the *Vateria Indica* of Linn., the *Elmacarpus copalifera* of Retzius; and the Brazilian, by Martius and Hayne, probably with justice, to different species of *Hymenaea*. There is some reason to believe that the East India copal is also the product of *Hymenaea*; at least a specimen of this resin was collected by M. Perrotet from the *Hymenaea verrucosa*, which he found growing in the Isle of Bourbon. This tree is a native of Madagascar, and probably of the neighbouring parts of Africa; and M. Perrotet was informed that the copal of India is taken thither by the Arabs of Muscat, who obtain it from the east coast of Africa. *(Journ. de Pharm., 3e sér., i. 406.)* It is stated by Mr. James Vaughan, who was stationed as army surgeon at Aden in Arabia, that copal is said to that port from the African coast opposite the island of Zanzibar, where it is said to be dug up from the earth. *(Pharm. Journ., xii. 385.)* In papers contained in the *Pharm. Journ.* (xvi. 369 and 423), Dr. W. F. Daniell has given an account of several varieties of copal produced on the coast and interior parts of Western Africa, from Sierra Leone to Angola and Benguela, and exported in large quantities. Those from Sierra Leone, which are most highly valued for their superior hardness and transparency, are said by Dr. Daniell to be derived from the *Guibourtia copalifera* of Bennett, a large tree, growing preferentially in mountainous regions, and very nearly related, botanically, to the *Hymenaea*, which produce copal in other regions. The drug is mostly collected, not from the tree itself, but from the beds and borders of streams, into which it is washed down, during the rains, from the hill-sides, in the soil of which it had been deposited. Copal varies in appearance and properties, as procured from different sources. It is in roundish, irregular, or flattish pieces, colourless, yellowish, or brownish-yellow, more or less transparent, very hard, with a shining, conchoideal fracture, inodorous and tasteless, of a sp. gr. varying from 1.045 to 1.139, insoluble in alcohol, soluble in ether and
slightly so in oil of turpentine. Some varieties unite with alcohol, if suspended in its vapour while boiling. By heat it melts and is partially decomposed, becoming thereby soluble in alcohol and oil of turpentine. It is not a proximate principle, but consists of various resins united in different proportions. The East India or African copal is described by Mr. Schindler as of a globular form, softer and more transparent than the other varieties, with a surface always clear, and having an agreeable smell when heated. It is readily and freely dissolved by the oils of turpentine and rosemary when pure, but not by these fluids when rendered resinous by age. It is more readily fusible than the others, and makes the best varnish. The West India copal is in flat pieces, seldom weighing more than three ounces, rarely containing insects, very hard, of a rough appearance, of a yellowish colour, and without smell or taste. It is much less readily dissolved by oil of turpentine than the East India variety, swells, but does not dissolve in oil of rosemary, and is slightly soluble in absolute alcohol. A third kind, probably also American, is in convex or concave pieces, about a pound in weight, often containing insects and other impurities. In solubility it resembles the last mentioned variety, in fusibility is intermediate between it and the East Indian, and is altogether inferior. (Pharm. Journ., Aug. 1850.) The African or Sierra Leone copal is described by Dr. Daniell as occurring "in small round tears, or irregular conical and smooth nodulated masses, seldom exceeding in size an ordinary duck egg. They are covered, to a greater or less extent, by a peculiar white efflorescence, which increases by age. Their colour graduates from a pale-green to a lemon or dull yellow." (Ibid., xvi. 809.)

**Copper, Black Oxide of.** This is the protoxide of copper, CuO, obtained most conveniently by heating to redness the nitrate. This oxide, in the form of ointment, made by mixing four parts with thirty of lard, has been used in frictions, practised twice a day, for the removal of chronic indurations of the glands. (Hoppe, Ann. de Thérap., 1855, p. 251.)

**Coral.** A substance found at the bottom of the Mediterranean and other seas, formerly considered as a plant, but now universally admitted to belong to the animal kingdom. This red coral (Corallium rubrum of Lamarck, Illis nobilis of Linn.) is in the form of a small shrub, a foot or two in height, with a stem sometimes an inch or two in thickness, fixed to the rock by an expansion of the base, divided above into branches, and covered with a pulpy membrane, which is properly the living part, and which is removed when the coral is collected. The central portion is extremely hard, of various shades of red, susceptible of a brilliant polish, longitudinally striated, and formed of concentric layers, which are rendered obvious by calcination. Its chief constituent is carbonate of lime, which is coloured by oxide of iron, and united, as in similar calcareous products, with more or less animal matter. It was formerly highly esteemed as a remedy, but is in no respect superior to prepared oyster-shell, or other form of carbonate of lime, derived from the animal kingdom. It was employed in fine powder, or in different preparations, such as troches, syrups, conserves, &c. At present it is valued chiefly as an ornament.

**Coralorrhiza Odontorrhiza.** (Gray's Manual, p. 453.) Coral-root. This is a leafless herb, sending up from a coral-like rhizoma, a simple scape or flower-stem, from 6 to 16 inches high, furnished with sheaths instead of leaves, of a light-brown or purplish colour, and bearing small, greenish-brown flowers in a long spike. The plant grows throughout the United States east of the Mississippi. It is supposed by some to be parasitic, attaching itself to the roots of trees, and nourished from them. The root or rhizoma is the part used. It is much branched and toothed, and of a brown colour, and from its resemblance to coral in appearance gave name to the plant. It has a strong peculiar odour, and an astringent bitterish taste. It holds a high place in the Materia Medica of the "eclectics," being considered by them as an energetic diaphoretic, and, as it is destitute of general stimulant properties, is given in fevers and inflammatory affections. It is administered in powder, in the dose of thirty grains, every two hours.

**Coriaria Myrtifolia.** Redout, Fr. This is a shrub indigenous in the south of France, and growing also wild in Spain, Italy, and Barbary. It is sometimes cultivated in gardens on account of its handsome foliage. The leaves, which are used for dyeing black, were at one time employed to a considerable extent in France in the adulteration of senna. The fruit, resembling berries in form, are black, and about the size of a pea. Both these and the leaves are poisonous in large doses, and several instances of death are on record from eating the fruit. They are supposed to act as a narcotic, as a child under their influence appeared, half an hour after taking them, as if in a state of drunkenness, with loss of speech, foaming at the mouth, livid face, and convulsive movements, and died at the end
of 17 hours. The stomach upon examination showed scarcely any signs of phlogosis. (Mérit et De Lens.) M. Ribain has discovered in the fruit a peculiar principle, on which he believes their poisonous properties depend, and to which he has given the name of cory-

amyrtin. This is in the form of white crystals, inodorous, excessively bitter, and extremely poisonous. It is but slightly soluble in water hot or cold, but freely so in alcohol, ether, chloroform, and benzole. Its composition is represented by the formula $\text{C}_{10}\text{H}_4\text{O}_{18}$. It ranks with the glycosides. About three grains of it killed a dog, first vomiting, then caus-

ing severe convulsions, and death in an hour and a quarter. M. Ribain obtained it by treating the juice of the fresh or an infusion of the dried fruit and leaves first with acetate of lead, then with sulphuretted hydrogen to throw down the lead, concentrating the filtered liquid to a syrupy consistence, and agitating this with ether, which extracted the poison, and yielded it on evaporation. (Journ. de Pharm., Juin, 1864, p. 487.)

Toot-poison. In New Zealand a poisonous plant, known as the tooth-plant, has proved very destructive to the domestic animals of the settlers. Dr. W. Lauder Lindsay, in a journey through New Zealand, had an opportunity of examining the plant and its effects. He found it to be the Coriaria ruscifolia of Linnaeus (C. sarmentosa, Först.), and in its action on the system to be an irritant narcotic.

W.

CORK. Suber, Lat. Liege, Fr. The great use made of this substance by the apothecary will justify a brief notice of it here. Though in general ascribed exclusively to the Quercus Suber, a large oak growing in Spain, the south of France, north of Italy, Algeria, and some of the Mediterranean islands, it is said by M. Casimer de Candolle to be obtained also for commercial purposes from another species, the Q. occidentalis, growing in the south-west of France and in Portugal. It consists of the exterior layers of the bark beneath the epidermis, which acquire in these species an extraordinary development, becoming thick, and of that peculiar spongy consistence which characterizes cork. The tree begins to yield cork when fifteen or sixteen years old, and every six or eight years furnishes a fresh supply, even for a century and a half, before it perishes; that interval of time being required for the renewal of the suberosae layers by the living portions of the bark beneath. There are four constituent layers of the bark, the epidermis, within this the cork, next the cel-

lular envelope, and lastly the liber which lies upon the wood. Each of these increases year by year; but the cork thus naturally produced is not valued. The commercial pro-
duct is obtained by an artificial process. The exterior layers are removed, and the liber exposed. In the interior of this, at a variable distance from the surface, a layer of the proper cork is now formed, apparently by a change in the substance of the liber, the outer portions of which perish, while annually a new layer is added to the cork already ex-

isting, until it acquires a thickness which will justify its removal. Incisions are made in such a way that the cork is removed in large coneave plates, which are then flattened under pressure, and dried very slowly. From ordinary accounts, it might be supposed that the cork-tree was very common in Spain; but in a long journey through that country from the North to the extreme South, the author had no opportunity of seeing the trees from which the cork was obtained except in the Eastern Pyrenees, where it appeared to be abundant.

In selecting cork for use, those parts should be preferred which are soft and of uniform consistence; and in the choice of the larger plates those should be selected which are thick, flexible, elastic, and finely porous, and of a reddish colour. (Guiouart.) Cork con-
sists mainly of a peculiar proximate principle analogous to lignin, but differing from it in this respect, that, when treated with nitric acid, it yields a peculiar acid, which has been denominated the suberic acid. According to M. Chevreul, who has analyzed cork, it con-
tains, besides the principle mentioned, a little volatile oil and acetic acid which it yields by distillation; a yellow colouring substance, an astringent principle, an animalized sub-
stance, gallic acid, another acid, gallate of iron and lime, all of which it yields to water; a wax-like crystallizable matter, a soft resin, and two other undetermined bodies, which were extracted by alcohol after having been exhausted by water; altogether constituting about 30 per cent., while the characteristic ingredient mentioned, which may be called suberin, amounts to 70 per cent.

W.

Cortex Caryophyllata. Cassia Caryophyllata. Clove Bark. These names have been given to a bark, brought from the West Indies, and derived from a tree belonging to the family of Myrtaceae, supposed to be the Myrtus acid of Schwartz. It is usually in cylinders from one to two feet long by an inch in diameter, composed of numerous separate pieces rolled around one another, having a dark-brown colour, a pungent taste, and an odour similar to that of cloves. It is sometimes in fragments, of a similar colour, taste, and smell, but softer and lighter, and supposed to be derived from older branches. A similar bark is said to be derived from the Myrtus caryophyllata of Linn., which grows in Ceylon. The clove bark has aromatic properties not unlike those of the spice from which it derived its name; but it is much inferior, and is not used in this country. Some authors have con-

founded with it a different bark, produced in the Moluccas, and known by the Indian name of cullilawan. (See Cullilawan.) W.
CORYDALIS FORMOSA. (Pursh.) Turkey Corn. Turkey Pen. This pretty little indigenous plant, growing in the Middle and Western States, is one of those employed by the practitioners calling themselves eclectics, and is highly esteemed by them. The root is the part used. It is a small roundish tuber, having a slight peculiar smell, and a bitterish somewhat pungent and persistent taste. It is said to yield its active properties to water and alcohol. According to Mr. W. T. Wenzell, who examined the root chemically, and made it the subject of an inaugural essay presented to the Philadelphia College of Pharmacy, it contains an alkaloid denominated corydaline, fumaric acid, bitter extractive, an acid resin with volatile oil, a tasteless resin, brown colouring matter, starch, albumen, arabin, bassorin, cellulose, and various inorganic salts. The alkaloid was obtained by making a hydro-alcoholic tincture, distilling off the alcohol, filtering, precipitating with ammonia in slight excess, washing the precipitate, treating it with boiling alcohol, evaporating the solution to dryness, treating the residue with dilute muriatic acid, precipitating with ammonia, dissolving the precipitate in boiling alcohol, concentrating the tincture, and allowing it to stand. The corydaline was deposited in crystals, and was purified by repeated solution in alcohol and crystallization. The crystals, which are slender four-sided prisms, are inodorous, tasteless, insoluble in water, soluble in alcohol, ether, and chloroform, reddened by nitric acid, and capable of forming soluble salts with the acids. It appears to be identical with the alkaloid found in European species of Corydalis. This has been examined by G. Leube, who gives, as the result of his analysis, the formula $C_{11}H_{14}NO_3$ as representing its composition.

The root is supposed to be tonic, diuretic, and alterative, and is given in syphilitic, scrofulous, and cutaneous affections, in the dose of from ten to thirty grains. It is also used in the form of tincture and decoction. We are indebted for the above abstract of the properties and uses of this plant to the essay of Mr. Wenzell, above referred to, published in the American Journal of Pharmacy for May, 1855, p. 206. The “eclectics” use a preparation which they call corydaline or corydaline made by precipitating a tincture of the root with water, in the dose of half a grain or a grain. It is of course not the active principle, and therefore has no claim to the title; yet it no doubt contains more or less of the proper alkaloid.

CORYLUS ROSTRATA. Beaked Hazel. This is a small indigenous shrub, growing especially in mountainous districts. The nut is invested with a scaly involucre, projecting beyond it like a beak, and thickly covered with short spicula like those of Mucuna pruriens. These spicula have been employed by Dr. Heubener, of Bethlehem, Pennsylvania, as an astringent, and found to be efficacious. They operate in the same way as cowslip, and may be administered in the same manner and dose. (See a communication by the late Mr. Duhamel, in the Am. Journ. of Pharm., xiv. 280.)

COTYLEDON UMBILICUS. Novel-wort. Penny-wort. This is a perennial, herbaceous, succulent plant, belonging to the class and order Decandria Pentagynia, and the natural family of Crupalaceae. It is about six inches high, with fleshy, peltate, crenate leaves, and a flower-stem bearing, in the form of a spike, pale-yellow, bell-shaped, pendulous flowers, which appear in June and July. The plant is a native of England, where it grows upon old walls and rocks, and dry sandy banks. It was first brought before the profession as a remedy in epilepsy, by Mr. Thos. Salter, of Poole, who had found its expressed juice very efficient in that disease, and published the results of his observations in the London Medical Gazette for March, 1849 (page 367). In the following May, Dr. Joseph Bullar, of Southampton, communicated the results of his observations on the same subject to the Proc. Med. and Surg. Journ., which were confirmatory of those of Mr. Salter. Since that period, other testimony has been advanced in favour of the remedy; among which is that of Dr. Graves, of Dublin, who considers it a valuable aid in the treatment of epilepsy, and states that it has long been known in Ireland as a popular remedy, not only in that disease, but in asthma. (Dublin Quart. Journ. of Med. Sci., xiv. 264.) It is, however, proper to say that Dr. Banking, of Norwich, England, in a letter published in the Lond. Med. Times and Gaz. for April, 1854 (page 328), declares that, so far as his experience goes, he considers the medicine utterly worthless, having employed it perseveringly in more than thirty cases of epilepsy, without the smallest benefit in a single instance.

The medicine is said to have no other observable effect than that of a gentle tonic to the nervous system. The part used is the expressed juice, which should be obtained when the leaves are most succulent, before the appearance of the flowers. An extract, and a fluid extract have also been employed. The juice has been given in doses varying from a fluid to a fluidounce twice or three times a day, and should be long persevered with. The dose of the fluid extract is stated at a fluidounce, that of the dry extract at two grains, to be increased if necessary.

CRABS’ CLAWS. Chelae Canerorum. These, in a prepared state, were formerly included in the Edinburgh Pharmacopoeia, but were very properly omitted upon the last revision of that work. Supposing them identical with the crust of the lobster, they consist, in the 100 parts, of 60 parts of carbonate of lime, 14 of phosphate of lime, and 26 of animal mat-
ter. They are prepared by levigation and elutriation, so as to bring them to a fine powder. They were formerly used as an absorbent and antacid; but the animal matter in their composition confers on them no peculiar virtues. They are given in the same dose with prepared chalk.

CRABSTONES. *Lapilli Cancrorum.* Crabs’ Eyes. These are concretions found in the stomach, one on each side, of the European crabfish, at the time the animal is about to change its shell. They are most abundantly procured in the province of Astrakan, in Asiatic Russia. The crabfish are bruised with wooden mallets and laid up in heaps to putrefy. The animal remains are then washed away, and the stones picked out. They are inodorous, insipid bodies, somewhat hemispherical in shape, of a white or reddish colour, hard and stony consistence, and laminated texture. They are very variable in size, weighing from one to twelve grains each. They effervesce with acids, and, without dissolving, become converted, owing to the animal matter which they contain, into a soft transparent mass, retaining the original shape of the stone. By this character they are distinguished from counterfeit stones, which are sometimes fabricated of chalk, mixed with mucilaginous substances. They consist of carbonate and phosphate of lime, cemented together by animal matter. Crabstones have been used as an absorbent and antacid, given in the same dose with prepared chalk. They were prepared by being levigated in the usual manner; but they are now no longer official, having been expunged from the Edinburgh Pharmacopeia.

CROCUS OF ANTIMONY. *Saffron of Antimony.* This compound is formed during the deflagration of a mixture of equal weights of tersulphuret of antimony and nitrate of potassa, to which one-twelfth of muriatic acid has been added. The nitric acid of the nitre is decomposed, nitrogen and nitric oxide being given off, and, by furnishing oxygen to part of the tersulphuret, converts its constituents into sulphuric acid and teroxide of antimony. The sulphuric acid combines with the potassa of the nitre, to form sulphate of potassa; while the teroxide unites or mixes with the undecomposed tersulphuret to constitute the crocus. The muriatic acid prevents the formation of sulphuret of potassium and free potassa, by giving rise to chloride of potassium. The product of the deflagration is reduced to powder, washed with boiling water to separate sulphate of potassa and chloride of potassium, and then fused. When crocus of antimony is intended to be employed for making tartar emetic, it should not be fused; because it requires, for preparing this antimonial, to be reduced to a very fine powder, and the fused substance is pulverized with difficulty. The deflagrated mass, instead of being fused, should be reduced to very fine powder, and washed with boiling water. In this state it more readily dissolves in the solution of cream of tartar. Fused crocus is in masses of a liver-brown colour. As obtained without fusion, it is a saffron-brown insoluble powder, containing about four-fifths of its weight of teroxide, the remaining fifth being tersulphuret. In the London Pharmacopeia of 1806, the unfused crocus was adopted for preparing tartar emetic; but in the edition of 1851 it was abandoned, and the subsulphate of antimony substituted for it.

CUCUMBER OINTMENT. An emollient ointment, prepared from the common cucumber (fruit of *Cucumis sativus*), has been considerably employed in irritated states of the skin. The following is the mode of preparing it, recommended by Prof. Procter. Take green cucumbers 7 pounds avoirdupois, pure lard 24 ounces, veal suet 15 ounces. Grate the washed cucumbers to a pulp, express, and strain the juice. Cut the suet into small pieces, heat it over a water-bath till the fat is melted out from the membrane; then add the lard, and, when melted, strain through muslin into an earthen vessel capable of holding a gallon, and stir until thickening commences, when one-third of the juice is to be added, and the whole beaten with a spatula till the odour has been almost wholly extracted. The portion which separates is to be decanted, and the remaining two-thirds of the juice are to be successively incorporated and decanted in the same manner. The jar is then closely covered and placed in a water-bath, until the fatty matter entirely separates from the juice. The green coagulum floating on the surface is now removed, and the jar put in a cool place that the ointment may solidify. The crude ointment is then separated from the watery liquid on which it floats, melted and strained, and placed in glass jars, which must be kept closely sealed. A layer of rose water upon its surface will favour its preservation. A portion may be triturated with a little rose water until white and creamy, and put into a separate jar for present use. (Am. Journ. of Phar., xxxv. 409.)

M. Emile Mouchon prepares the ointment by obtaining the juice mixed with a little alcohol, and incorporating this with benzinated lard and stearin. He directs 16 parts of the cucumber to be reduced to a pulp, 1 part of alcohol of 36° B. to be added, and the mixture to be placed on the diaphragm of a percolator. Twenty-four hours afterwards 10 parts of the liquid are obtained of 10° B. Of this liquid 6 parts are to be incorporated with 37-5 parts of benzinated lard and 12-5 of stearin; the fatty matters having been previously melted together by means of a water-bath, and beaten vigorously on cooling. The liquid is to be added before the completion of the beating, which should then be continued, until
PART III.  Cucurbita Citrullus.—Cuttle-fish Bone.  1507

the whole becomes as light and white as possible. The benzoin and alcohol enable the ointment to keep a long time. (Journ. de Pharm., Juillet, 1854, p. 41.)

CUCURBITA CITRULLUS. Watermelon. The seeds of the watermelon are employed, to a considerable extent, as a domestic remedy in strangury and other affections of the urinary passages. They have similar properties with the seeds of the other Cucurbitaceae, of which four different kinds were formerly official under the name of the greater cold seeds—viz., those of the Cucurbita Pepo or pumpkin, the Cucurbita Lagenaria or gourd, the Cucumis Melo or muskmelon, and the Cucumis sativus or cucumber. These, when bruised and rubbed up with water, form an emulsion, which was formerly thought to possess considerable virtues, and was much used in catarrhal affections, disorders of the bowels and urinary passages, fever, &c.; but they have been superseded by other more agreeable demulcents. Watermelon seeds are also esteemed by some diuretic. They are given in infusion, made with one or two ounces of the bruised seeds to a pint of water, and taken ad libitum. The juice of the melon itself is undoubtedly diuretic, and might be very properly recommended as an adjuvant to other remedies in many cases of dropsey.

The pulp of the root of Cucurbita Lagenaria or gourd is said by Dr. Chapin to be a powerful and even drastic purgative, and to be used by the natives of the Sandwich Islands successfully in dropsey; though in the large quantities in which it is used by them, it sometimes proves fatal through hyperaetharsis. (See a paper by Dr. Luther H. Gulick, in the N. Y. Journ. of Med. for March, 1855, p. 208.)

CULLILAWAN. Cortez Culilaban. An aromatic bark, produced by Cinnamomum Cullilawan (Laurus Culilawan, Linn.), a tree of considerable size, growing in the Molucca Islands, Cochín China, and other parts of the East. It is usually in flat or slightly rolled pieces, several inches long, an inch or more in breadth, and one or two lines thick. Sometimes the bark is thinner and more quilled, bearing considerable resemblance to cinnamon. The epidermis is for the most part removed, but when present is of a light brownish-grey colour, soft to the touch, and somewhat spongy. The colour of the bark itself is a dull dark cinnamon-brown, the odour highly fragrant, the taste agreeably aromatic, and not unlike that of cloves. The active constituent is a volatile oil, which may be separated by distillation. Culilawan has the medical properties common to the aromatics, but is scarcely used at present.

CUMIN SEED. CUMINUM, Lond. CUMINUM, Ed. Cumin seeds have been omitted in the British Pharmacopoeia, and, having no place in our own, and consequently none in Part I. of this work, require a brief notice here. They are the fruit of the Cuminum Cuminum, an umbelliferous plant, belonging to Pentandria Digynia of the Linnaean system, with the following generic character. "Fruit ovate, striated. Partial umbela four. Involute four-cleft." (Wld.) It is an annual plant, about six or eight inches high, having a round, slender, branching stem, with numerous narrow, linear, pointed, smooth, grass-like leaves, of a deep-green colour. The flowers are white or purple, and disposed in numerous terminal umbels, which have very few rays, and are attended with general and partial involucres, consisting of three or four linear leaflets. The fruit consists of two oblong plano-convex half-fruits, commonly called seeds, united by their flat sides. The plant is a native of Egypt, but is cultivated for its fruit in Sicily, Malta, and other parts of Europe.

The cumin seeds of the shops are elliptical, flat on one side, convex, furrowed, and rough on the other, about one-sixth of an inch in length, and of a light-brown colour. Each has seven longitudinal ridges. Two seeds are sometimes united together as upon the plant. Their colour is peculiar, strong, and heavy: their taste warm, bitterish, aromatic, and disagreeable. They contain much essential oil, which is lighter than water, yellowish, and has the sensible properties of the seeds. It consists of two distinct oils, one a carbohydrogen, called cymene (C₉H₁₃), the other consisting of carbon, hydrogen, and oxygen (C₂H₆O₂), which may be regarded as hydrate of cymyl (C₂H₆O₂·H). (Gregory's Organic Chemistry, 4th ed., pp. 356 and 341.) In medical properties cumin seeds resemble the other aromatic fruits of umbelliferous plants, but are more stimulating. They are seldom used in the United States, and appear to have been retained by the London College merely as an ingredient in a stimulant and dissective plaster (Emplastrum Cuminum), now no longer official. The dose is from fifteen grains to half a drachm.

CUNILA MARIANA. American Dittany. A small indigenous perennial herb, growing on dry, shaly hills, from New England to Georgia, and flowering in June and July. The whole herb has a warm pungent taste, and a fragrant odour, dependent on an essential oil. Its medical properties are those of a gently stimulant aromatic, analogous to the mints, pennyroyal, &c. In warm infusion, it is popularly employed to excite perspiration in colds and slight fevers, to promote suppressed menstruation, to relieve flatulent colic, and for various other purposes to which the aromatic herbs are thought applicable.

CUTTLE-FISH BONE. Os Sepiae. This is a calcareous body, situated underneath the skin, in the back of the Sepia officinalis, or cuttle-fish, which inhabits the seas of Europe, especially the Mediterranean, in the waters of which the bone is not unfrequently found.
Cyanide of Zinc.—Cyananum Vincetoxicum.  

PART III.

floating. It is oblong-oval, from five to ten inches long, and from one and a half to three inches broad, somewhat convex on both sides, with thin edges, of a rather firm consistence upon the upper surface, very friable beneath, and composed of numerous layers, loosely connected, so as to give to the mass a porous consistence. It is lighter than water, of a white colour, a feeble odour of sea plants, and a saline taste. It contains, according to John, from 80 to 85 per cent. of carbonate of lime, besides animal matter, a little common salt, and traces of magnesia. Reduced by levigation and elutriation to a fine powder, it may be given as an antacid like chalk or oyster-shell. It is sometimes used as an ingredient of tooth-powders. Small pieces of it are often put into bird-cages, that the birds may rub their bills against them; and the powder is employed for polishing. Another product of the cuttle-fish is a blackish-brown liquor, secreted by a small gland into an oval pouch, communicating externally near the rectum by a long excretory duct, through which the animal is said to have the power of ejecting it at will. This, when taken from the fish, is dried, and used in the preparation of the water colour called sepia.

CYANIDE OF ZINC. Zinci Cyanidum. Cyanuret of Zinc. This cyanide is precipitated as a white insoluble powder, by adding cautiously, until it ceases to produce a precipitate, a recently filtered solution of cyanide of potassium, obtained from the impure black cyanide, to a solution of sulphate of zinc. It is used in Germany as a substitute for hydrocyanic acid, and is said to be anthelmintic. It has been employed in epilepsy, chorea, and neuralgia, in several painful affections of the stomach, and in the colics attendant on difficult menstruation. The dose is a quarter of a grain, gradually increased to a grain and a half, given in mixture. It is included in the official list of the French Codex.

CYCLAMEN EUROPÆUM. Pain de Porceau, Fr. Sow-bread. This is an herbaceous perennial, stemless plant, indigenous in the south of Europe, and cultivated in gardens for the beauty of its purple flowers, with reflected petals. It belongs to Pentandria Monogynia of the Linnean system, and to the natural order Primulaceae. The root is globular, with many branched fibres, almost black without, and white within, inodorous, and, when fresh, of a bitter, acrid, burning taste. By drying it loses much of its acrimony, and is said to be rendered edible by roasting. Hogs are said to root it up from the ground and to eat it with impunity; and hence its common French name. The root is a drastic cathartic, and is thought to have the power of producing abortion, for which purpose it is sometimes employed among the peasantry, who habitually use it as a cathartic. Sometimes, however, it has produced very serious effects, as inflammation of the alimentary canal, with bloody stools, cold sweats, and convulsive movements, which have even ended fatally. It is supposed to be capable of acting on the bowels when applied to the skin; and, in the form of ointment, is said to be rubbed on the surface of the abdomen in children for the expulsion of worms. (Mérat and De Lens.) The root probably owes its acrimony, if not all its medicinal properties, to an active principle, first discovered many years since by Saladin, and named by him arthanaïn, and more recently by S. De Luca, who has given it the more appropriate name of cyclamin. It is white, amorphous, inodorous, and when held a short time in the mouth intensely acrid, extending its action even to the throat. With cold water it swells and becomes gelatinous, but is readily dissolved, and forms a solution which froths like soap and water, and is coagulated by a heat of about 150° F. Alcohol dissolves it with difficulty when cold, but freely when hot; it is soluble in glycerin with the aid of heat; and is insoluble in ether, chloroform, bisulphuret of carbon, and the essential oils. It contains no nitrogen; its formula being, according to an analysis by Dr. Klinger, CsH₆O₁₅. Dr. T. W. C. Martius recommends the following method of preparing it. The tubers, collected in the autumn, dried, and powdered, are mixed with animal charcoal, and exhausted at a boiling heat by alcohol of 0'825; the tincture is filtered, concentrated, and set aside for six or eight weeks, when the cyclamin is deposited. This should be washed on a filter with an alkaline spirit to pass over it, and if the filtrate be concentrated, and set aside, it will deposit a further quantity in a few weeks. The whole is then mixed with animal charcoal, and treated with boiling alcohol, which will slowly deposit the pure cyclamin on cooling. This principle was found by M. De Luca, by experiments on animals, to be poisonous, and he supposed it to resemble curari in its action, though less violent.  (See Am. Journ. of Pharm., Jan. 1858, p. 21, and March, 1860, p. 164.) The dose of the powdered root is said to be from 20 to 40 grains.

CYANANCHUM VINCETOXICUM. R. Brown. Asclepias Vincetoxicum. Linn. White Swallow-wort. Vincetoxicum. A perennial herbaceous European plant, the root of which was formerly esteemed a counterpoison, and hence gave origin to the official name. It has a bitterish acrid taste, and, when fresh, a disagreeable odour which is diminished by drying. Taken internally, especially in the recent state, it excites vomiting, and is capable, in large quantities, of producing dangerous if not fatal inflammation of the stomach. Its former reputation as an alexipharmic was without foundation. It is said to be useful in cutaneous diseases, scrofula, &c., but is little employed. The leaves of the plant also are emetic. Peneuile found in the root a peculiar principle analogous to emetin.
PART III.  

Cynara scolymus.—Dianthus Caryophyllus.  

1509

CYNARA SCOLYMUS. Garden Artichoke. This is a perennial plant, indigenous in the south of Europe, and cultivated in our gardens as a culinary vegetable. The flowers, constituting what are commonly called the heads, are the parts used. The receptacle and the lower portion of the fleshy leaflets of the calyx are eaten, and the other parts rejected. When young, the heads are cut up raw and eaten as salad; when older, they are boiled, and dressed variously. The flowers are said to curdle milk, and the plant to yield a good yellow dye. The leaves and their expressed juice are very bitter, and have been thought to be actively diuretic. They have long had some reputation in the treatment of dropsies. Dr. Badely, of Chelmsford, England, recommends a tincture and extract, prepared from the leaves, in rheumatic, gouty, and neuralgic affections. He gives a drachm of the tincture, with five grains of the extract, three times a day, with or without other remedies as circumstances seem to require. The leaves should be fresh, and the preparations made from them quickly used. (Lond. Lancet, 1843, p. 556.)

W.

CYNOGLOSSUM OFFICINALE. Hound’s Tongue. A biennial plant, common both in Europe and this country, and named from the shape of its leaves. The leaves and root have been employed, but the latter has been generally preferred. The fresh plant has a disagreeable narcotic odour resembling that of mice, which is dissipated by drying. The taste is nauseous, bitterish, and mucilaginous. Different opinions as to its powers have been entertained, some considering it nearly inert, others as a dangerous poison. Hound’s tongue has been used as a demulcent and sedative in coughs, catarrh, spitting of blood, dysentery, and diarrhoea; and has been applied externally in burns, ulcers, scrofulous tumours, and goitre. The pilula de cynoglosso, which are official in some parts of Europe, though they contain the root of hound’s tongue, owe their properties chiefly to opium. W.

CYTISUS LABURNUM. Laburnum. The laburnum is a small tree, indigenous in the higher mountains of Europe, and cultivated, throughout the civilized world, in gardens and pleasure grounds for the beauty of its flowers, which appear early in the spring in rich pendent yellow clusters. The young shoots and probably the leaves, indeed all parts of the plant are purgative, and in excessive doses poisonous. Caventou found in the flowers an odorous fixed oil, gum, lignin, gallic acid, and traces of sulphate and muriate of lime. MM. Chevallier and Lassaigne discovered in the seeds a peculiar principle, to which they gave the name of cytisin. This was a yellowish-white, neutral, amorphous, deliquescent, non-nitrogenous substance, of a bitter nauseous taste, soluble in water and weak alcohol, and insoluble in ether. In small doses it produced, in several animals of different species, vomiting, convulsions, and death; and eight grains taken by Chevallier himself caused threatening symptoms, which disappeared under the free use of lemonade. Five grains appeared equal to three of tartar emetic. (Mérat et De Lenc.) Dr. Th. Scott Gray has recently undertaken the examination of the laburnum, and has found three distinct principles, an acid which he names laburnic, and two other substances, both of them bitter and neutral, which he proposes to call laburnum and cystine. These are contained in variable proportions in all parts of the plant, but most largely in the bark and seeds. As all of them are soluble in water and only a portion of them in alcohol, the former is the proper menstruum for extracting the virtues of the plant. In reference to the effects on the system, Dr. Gray found that, after a slight excitement of the nervous and circulatory systems, there was a diminution of the pulse and a disposition to sleep. Decided narcotic effects were produced, with a moderate increase of urine, and a tendency to increased action of the liver. Dr. Gray employed the preparations of the plant therapeutically, and found them useful in bilious dyspepsia, with periodical vomiting and alternations of constipation and diarrhoea; in infantile vomiting; in allaying the cough in bronchitis, and the violence of the paroxysms of hooping-cough and asthma; in the vomiting of pregnancy; and, finally, given in large doses four times a day, in the treatment of prurigo; the decoction being at the same time applied externally. (Pharm. Journ., Août, 1862, p. 160, from the Ed. Med. Journ.) Several cases of poisoning from laburnum seeds have recently been recorded. In a child about six years old, taken to the Cork Infirmary, the symptoms were gidiness and pain in the head, dryness and constriction of the throat, afterwards very painful sensations in the heart and stomach, followed by nausea and vomiting, with rapid and fluttering pulse, laboured breathing, convulsive twitchings of the face, and wide dilatation of the pupils and insensibility to light. He recovered, however, under treatment. (J. Popham, Dublin Quart. Journ. Feb. 1868, p. 248.) Another case is reported as having occurred at Canterbury, England, in which very similar symptoms resulted from the same cause, and with a similar result. (Med. Times and Gaz., Sept. 13, 1862.)

W.

DIANTHUS CARYOPHYLLUS. Clove Pink. The clove pink or carnation is too well known to require minute description. It is a perennial, herbaceous plant, belonging to the family of Caryophyllaceae, and characterized as a species by its branching stem, its solitary flowers, the short ovate scales of its calyx, its very broad heartless petals, and its linear, subulate, channeled, glaucous leaves. Indigenous in Italy, it is everywhere cultivated in gardens for the beauty of its flowers, of which numerous varieties have been produced by
horticulturists. Those are selected for medicinal use which have the deepest red colour, and the most aromatic odour. The petals should not be collected till the flower is fully blown, and should be employed in the recent state. They have a fragrant odour, thought to resemble that of the clove. Their taste is sweetish, slightly bitter, and somewhat astringent. Both water and alcohol extract their sensible properties, and they yield a fragrant essential oil by distillation. In Europe they are employed to impart colour and flavour to a syrup, which serves as a vehicle for other less pleasant medicines. According to the direction of the former Edinburgh Pharmacopoeia, this was prepared by macerating one part of the flowers, without their claws, with four parts of boiling water for twelve hours, then filtering, and adding seven parts of sugar.

**Diphoretic Antimony.** Antimonium Diphoreticum. Potassa Biantimonias. This compound is directed, in the French Codex, to be formed by deflagrating in a red-hot crucible, and keeping red-hot for half an hour, a mixture of pure antimony with twice its weight of nitrate of potassa, both being in fine powder. The product is washed with water and dried, and forms the washed diaphoretic antimony. As thus prepared, M. Oscar Figuier has shown that it contains, besides antimoniac acid, both tetroxide of antimony and antimonious acid; the nitre not being in sufficient quantity completely to peroxitize the antimony. When, however, the antimony is deflagrated with three times its weight of nitre, and the matter is kept at a red heat for an hour and a half, the whole of the antimony is converted into antimoniac acid; and, when the product is thoroughly exhausted by boiling water, the resulting solution contains a large quantity of neutral antimoniate of potassa, and the insoluble residue is impure biantimoniate. M. Figuier rejects this residue, which forms the diaphoretic antimony of the ordinary process, and obtains the preparation from the solution of the neutral antimoniate, by passing through it a stream of carbonic acid gas, which removes one eq. of potassa from two of the antimoniate, and throws down the biantimoniate in the form of a white powder. By this process he obtained a quantity of the preparation, equal to three-fourths of the weight of the materials employed. Diaphoretic antimony is a perfectly white powder. When properly prepared, as by the process of M. Figuier, it consists of two eqs. of antimoniac acid, one of potassa, and six of water. The dose is two or three drachms. On account of its weak and variable nature, it has been generally laid aside in practice.

**Dictamus Albus.** White Frazinella. Bastard Dittany. This is a perennial European plant, the root of which is bitter and aromatic, and has been used as an anthelmintic, emmenagogue, and stomachic tonic; though at present little employed in Europe, and not at all in this country. Störek gave it in intermittent, worms, amenorrhoea, hysteria, epilepsy, and other nervous diseases. The bark of the root is the most active part. The dose is from a scruple to a drachm.

**Diervilla Trifida.** (Meench, Gray’s Manual, p. 166.) D. Canadensis. (Muhl.) Bush Honeysuckle. A low, erect, indigenous shrub, growing especially in rocky places throughout the Northern States. The whole plant, including root, branches, and leaves, is supposed to be possessed of diuretic and astringent properties, which render it useful, given in the form of infusion, in diseases of the urinary passages. It is one of the eclectic remedies.

**Dioscorea Villosa.** (Gray’s Manual, p. 480.) Wild Yam-root. Colic-root. An indigenous perennial creeper, with long, branching, conorted, fibrous, ligneous roots. It grows from Maine to Wisconsin, and southward also. The roots are used by the “eclectics” who consider them efficacious in bilious colic. They are administered in decoction and tincture; and a substance called improperly Dioscorin, obtained by precipitating the tincture with water, is used for the same purpose in a dose of from one to four grains.

**Dipple’s Animal Oil.** Oleum Cornu Cervi. This oil is obtained during the distillation of bones, in the processes for obtaining ammoniacal products on a large scale. The portion which first comes over is pale-yellow; but, in the progress of the distillation, the distillate becomes gradually deeper coloured and thicker, and at last black and viscid. It is purified and rendered colourless by redistillation, a pyrogenic resin being left behind. Thus rectified it is a colourless liquid, very limpid and volatile, with a penetrating extremely fetid odour and burning taste. By repeating the distillation till a dark residuum is no longer left in the retort, it may be obtained free from fetor, and of an agreeable, aromatic odour; and in this mode it is said to have been prepared by Dipple. Four or five distillations are necessary. (Am. Journ. of Pharm., ix. 244.) The oil is soon altered by the action of air and light, becoming thick, yellow, brown, and finally black. It has an alkaline reaction, and probably contains the various principles which have been discovered by Reichenbach in the products of the distillation of organic substances.

This oil was originally obtained from hartshorn, and was a product of the decomposition of the gelatinous tissue, the horn containing no fat. When obtained from bones, it is a product of the same tissue; as these are boiled with a large quantity of water, and dried, before they are submitted to destructive distillation. The oily product of this distillation, after rectification, forms the bone-oil of commerce. Bone-oil has a dark-brown almost black colour, with a greenish shade. It is perfectly opaque in the mass, but brown when viewed by trans-
mitred light in a thin layer. Its sp. gr. is about 0·970. Its smell is peculiarly disagreeable and somewhat ammoniacal. A piece of fir-wood, moistened with muriatic acid, and held over the mouth of a vessel containing it, acquires a dark reddish-purple colour, characteristic of pyrrol. It contains several organic bases, such as picolin, piconin, &c., which have been examined by Dr. Thomas Anderson, of Scotland. (See his paper on the distillation of animal substances, in the Philos. Mag., 3d series, xxx. 174; and for a notice of picolin, see the note in page 648.)

Animal oil was formerly much used in medicine; but its repulsive odour and taste, as it is ordinarily prepared, have caused it to be almost entirely laid aside. It is given in the dose of a few drops, mixed with water, and acts as a stimulant and antispasmodic. Its presence in the spirit and salt of hartshorn gives these preparations medicinal properties different from those of the pure spirit and of carbonate of ammonia.

B. DIRCA PALUSTRIS. Leather Wood. An indigenous shrub, usually very small, but sometimes attaining the height of five or six feet, growing in boggy woods, and other low wet places, in almost all parts of the United States. The berries, which are small, oval, and of an orange colour, are said to be narcotic and poisonous. The bark has attracted most attention. It is extremely tough, and of very difficult pulverization. In the fresh state it has a peculiar rather nauseous odour, and an unpleasant acid taste, and when chewed excites a flow of saliva. It yields its acromy completely to alcohol, but imperfectly to water even by decoction. In the dose of six or eight grains, the fresh bark produces violent vomiting, preceded by a sense of heat in the stomach, and often followed by purging. Applied to the skin it excites redness and ultimately vesiculates; but its epispastic operation is very slow. It appears to be analogous in its properties to mezereon, to which it is botanically allied.

W. DRAGON'S BLOOD. Sanguis Draconis. This is a resinous substance obtained from the fruit of several species of Calamus, especially C. Rotang, and C. Draco, small palms, growing in Siam, the Molucca Islands, and other parts of the East Indies. On the surface of the fruit, when ripe, is an exudation, which is separated by rubbing, or shaking in a bag, or by exposure to the vapour of boiling water, or finally by decoction. The finest resin is procured by the two former methods. It comes in two forms: sometimes in small oval masses, of a size varying from that of a hazelnut to that of a walnut, covered with the leaves of the plant, and connected together in a row like beads in a necklace; sometimes in cylindrical sticks, eighteen inches long and from a quarter to half an inch in diameter, thickly covered with palm leaves, and bound round with slender strips of cane. In both these forms, it is of a dark reddish-brown colour, opaque, and readily pulverizable, affording a fine scarlet powder. It sometimes comes also in the form of a reddish powder, and in small irregular fragments or tears. An inferior kind, said to be obtained by boiling the fruit in water, is in flat circular cakes, two or three inches in diameter and half an inch thick. This also yields a fine red powder. A fourth variety, much inferior even to the last mentioned, is in large disks, from six to twelve inches in diameter, by an inch in thickness, mixed with various impurities, as pieces of the shell, stem, &c., and supposed to be derived from the fruit by decoction with expression. A substance known by the name of dragon's blood is derived by exudation from the trunk of Dracaena Draco, a large tree inhabiting the Canary Islands and the East Indies, and another from Pterocarpus Draco, a tree of the West Indies and South America, by incision into the bark. These last, however, are little known in commerce. According to Lieut. Wellstead, much dragon's blood is obtained in the island of Socotra, by spontaneous exudation from a large tree, growing at a considerable elevation on the mountains.

Dragon's blood is inodorous and tasteless, insoluble in water, but soluble in alcohol, ether, and the volatile and fixed oils, with which it forms red solutions. According to Herberger, it consists of 90-7 parts of a red resin, which he calls dracoonin, 2·0 of fixed oil, 3·0 of benzoic acid, 1·6 of oxalate of lime, and 3·7 of phosphate of lime. It was formerly employed in medicine as an astringent, but is nearly or quite inert, and is now never given internally. It is sometimes used to impart colour to plasters, but is valued chiefly as an ingredient of paints and varnishes.

W. DUTCH PINK. A yellow or brownish-yellow paint, consisting of clay, or a mixture of clay and chalk, or carbonate of lime in the form of whiting, coloured by a decoction of wood, French berries, or birch leaves, with alum.

W. EMERY. A very hard mineral, the powder of which is capable of wearing down all other substances except the diamond. As existing in commerce, it is said to be derived chiefly from the island of Naxos, in the Grecian Archipelago; but, according to Landerer, it has been found also in Asia Minor and the Morea. It is pulverized by grinding it in a steel mill, and the powder is kept in the shops of different degrees of fineness. It is used for polishing metals and hard stones. The method, adopted in Smyrna, of ascertaining its purity, is to rub a plate of glass of known weight with a certain quantity of the suspected mineral
until it ceases to have any effect. The loss of weight in the glass is the measure of the value of the emery. (See Am. Journ. of Pharm., March, 1862, p. 187.)

**EPIGAEA REPENS.** Trailing Arbutus. Ground Laurel. May-flower. This is a small trailing plant, with woody stems from six to eighteen inches long, entire, cordate-ovate leaves, and small, very fragrant flowers, which appear early in the spring. It is found in the woods, and affects the sides of hills with a northern exposure. Dr. Darlington states that the plant has been supposed to be injurious to cattle, when eaten by them. (Flora Cestrica, p. 269.) The late Dr. Eli Ives, of New Haven, Connecticut, furnished us with the following account of its virtues and uses, founded on his own observation. "The Epigaea repens has been freely used for some years in diseases of the urinary organs, and of the pelvis viscera generally, particularly of irritated action, in those cases in which the uva ursi and buchu are indicated. The leaves and stems are prepared in the same manner, and administered in the same dose as the uva ursi. The Epigaea has given relief in some cases where the uva ursi and buchu have failed. May 4th, 1849."

**EPILOBIOU ANGUSTIFOLIUM.** (Gray's Manual, p. 130.) Willow-herb. There are several species of Epilobium, which have the common name of willow-herb from the resemblance of their leaves to the willow, and probably have nearly identical properties. They are all perennial and indigenous. The E. angustifolium is the largest of them, having a simple stem, from four to seven feet high. It is common in the Northern States, frequenting low, or newly-cleared grounds. It bears showy purple flowers, which appear in July and August. The leaves and roots are said to be demulcent, tonic, and astringent, and yield their virtues to water and alcohol. They are used by the "eclectics," generally and locally, in decoction, infusion, or cataplasm, in cases which call for the use of astringent remedies.

**EQUISETUM HYEMALE.** (Gray's Manual, p. 585.) Horsetail. Scouring Rush. An indigenous cryptogamous plant, with slender annual stems from 18 inches to 3 feet high, growing abundantly in the Northern States, and preferring wet places, as the banks of streams, &c. The plant derives its name of scouring rush from its use in scouring, for which it is fitted by the siliceous character of the stems. It has the reputation of being diuretic, and is used sometimes in dropscial diseases and those of the urinary passages. The whole plant is employed, usually in the form of infusion.

**ERECHTHITES HIERACIFOLIA.** (Gray's Manual, p. 290.) Fireweed. An annual indigenous plant, growing in moist woods and recent clearings, and having a rank odour, though somewhat aromatic, which probably called attention to the plant in reference to its use in medicine. Its taste is bitterish, slightly acrid, and disagreeable. It yields these and what medical virtues it may possess to water. It has been especially recommended in dysentery. This plant is apt to infest the peppermint fields of Michigan; and its oil is said sometimes to deteriorate the oil of peppermint from that region.

**ERYNGIUM AQUATICUM.** Button Snakeroot. The root of Eryngium aquaticum was recognised as official in the Secondary Catalogue of the U. S. Pharmacopoeia, until the recent revision, when it was dismissed. The plant belongs to Pentandria Digynia of the Linnæan system, and to the natural order Apiaceae or Umbelliferae. The following is its generic character. "Flowers capitate. Involucrum many-leaved. Proper calyx five-parted, superior, persistent. Corolla of five petals. Receptacle foliaceous, segments acute or cuspidate. Fruit bipartite." (Nuttall.) The button snakeroot or water eryngio is an indigenous herbaceous plant, with a perennial tuberous root, and a stem two or three feet high, sometimes, according to Pursh, six feet, generally branching by forks, but trichotomous above. The leaves are very long, linear-lanceolate on the upper part of the stem, sword-shaped below, with bristly spines at distant intervals upon their margin. The floral leaves are lanceolate and dentate. The flowers are white or pale, and in globose heads, with the leaflets of the involucre shorter than the head, and, like the scales of the receptacle, entire. This plant is found in low wet places, as far south as Virginia and N. Carolina. Its period of flowering is August. The root, which is the medicinal portion, has a bitter, pungent, aromatic taste, provoking, when chewed, a flow of saliva. It is diaphoretic, expectorant, in large doses occasionally emetic; and is used by some physicians in decoction as a substitute for seneka. (Bigelow.) We are told in Barton's Collections, that it is nearly allied to the contrayerva of the shops.

**ERYTHRIONIUM AMERICANUM.** (Muhl. Catalogue, 84; Bigelow, Am. Med. Bot., iii. 151.)—E. lancolatum. (Pursh, p. 320.) The root and herb of this plant were official in the U. S. Pharmacopoeia, in which they occupied a place in the Secondary Catalogue until the late revision. The plant belongs to Hexandria Monogynia in the Linnæan system, and to the natural order of Liliaceae. The following is the generic character. "Calyx none. Corolla inferior, six-petaled; the three inner petals with a callous prominence on each edge near the base." (Bigelow.) This is an indigenous perennial bulbous plant, sometimes called, after the European species, dog's tooth violet. The bulb (cornus), which is brown externally, white and solid within, sends up a single naked slender flower-stem, and two smooth, lanceolate, nearly equal leaves, sheathing at their base, with an obtuse callous point, and of a brownish-
PART III.

Erythroxylon Coca.

green colour diversified by numerous irregular spots. The flower is solitary, nodding, yellow, with oblong-lanceolate petals obvate at the point, a club-shaped undivided style, and a three-lobed stigma. The Erythroxylum grows in woods and other shady places throughout the Northern and Middle States. It flowers in the latter part of April or early in May. All parts of it are active. In the dose of twenty or thirty grains, the recent bulb operates as an emetic. The leaves are said to be more powerful. The activity of the plant is diminished by drying.

ERIHYTHROXYLON COCA (Lamarck). Coca. This is a shrub growing wild in South America, and largely cultivated in Bolivia for the sake of its leaves, which are much used in that country as a masticatory. The plant is propagated from the seed in nurseries, which begin to yield in eighteen months, and continue productive for half a century. The leaves, on being picked, are dried in the sun, and then packed in bags. They are known in South America by the name of coca. This was in general use among the natives of Peru at the time of the conquest, and has continued to be much employed to the present time.

The leaves resemble in size and shape those of tea, being oval-oblong, pointed, two inches or more in length by somewhat over an inch in their greatest breadth, and furnished with short delicate footstalks; but they are not, like the tea leaves, dentate, and are distinguished from most other leaves by a slightly curved line on each side of the midrib, running from the base to the apex. When well dried, they have an agreeable odour resembling that of tea, and a peculiar taste, which, in decoction, becomes bitter and astrigent. Some attempts were made to analyze coca before the publication of the eleventh edition of this Dispensatory, of which the main result was, that the leaves contained a peculiar very bitter principle on which their virtues probably depended. M. Stanislas Martin afterwards made a hasty examination, from which it appeared that they contain a peculiar bitter principle, resin, tannin, an aromatic principle, extractive, chlorophyll, a substance analogous to their, and salts of lime. (Journ. de Pharm., Avril, 1859, p. 283.) Dr. Albert Niemann, of Goslar, has made a more thorough investigation of the leaves, and succeeded in isolating a peculiar alkaloid, to which he gives the name of eocaina. The following was his process. The leaves were exhausted with 85 per cent. alcohol acidulated with 2 per cent. of sulphuric acid; the mixture was treated with milk of lime and filtered; the filtrate was neutralized with sulphuric acid, and the alcohol distilled off. The syrupy residue was treated with water to separate resin, and then precipitated by carbonate of soda. The deposited matter was exhausted by ether, and the ethereal solution, after most of the ether had been distilled, was allowed to evaporate spontaneously. The cocaine was thus obtained in colourless crystals, mixed with a yellowish-brown matter of an disagreeable odour, which was separated by washing with cold alcohol. Pure cocaine is in colourless transparent prisms, inodorous, of a bitterish taste, soluble in 704 parts of cold water, more soluble in alcohol, and freely so in ether. The solution has an alkaline reaction, and a bitterish taste, leaving a peculiar numbness on the tongue, followed by a sensation of cold. The alkaloid melts at 208° F., and on cooling congeals into a transparent mass, which gradually becomes crystalline. Heated above this point it changes colour, and is decomposed. It is inflammable, burning with a bright flame, and leaving charcoal. With the acids it forms soluble and crystallizable salts, which are more bitter than the alkaloid itself. It was found to consist of carbon, hydrogen, nitrogen, and oxygen; and the formula as given by Dr. Niemann is C_{21}H_{22}N_{2}O_{2}. He also obtained wax, a variety of tannic acid (coecattanic acid), and a concrete volatile odorous substance. (See Am. Journ. of Pharm., March, 1861, p. 122.) Mr. Maisch, of Philadelphia, succeeded in obtaining from the leaves an uncrystallizable alkaloid, having so nearly the properties of cocainas that he considered it merely as the result of the action of heat on the crystallizable principle. (Ibid., Nov. 1861, p. 500.) Still more recently M. Lossen has examined cocainas, and ascertained that, when heated with muriatic acid, it splits into benzoic acid and a new base which he calls eogomin. The mutability of cocainas with acids, explains why the attempts to extract the alkaloid with acid liquors have failed. M. Lossen therefore recommends the omission of acid in operating on the leaves, and proposes the following modification of Niemann's plan. An infusion is first made; this is precipitated with acetate of lead; the lead is removed by sulphate of soda; the liquid is concentrated, carbonate of soda added, and the whole shaken with ether. The ether extracts the alkaloid, and yields it in a crude state by evaporation. It is then purified as in the process of Dr. Niemann. (Journ. de Pharm., Juin, 1862, p. 522.)

According to Dr. Weddell, coca produces a gentle exciting effect, with an indisposition to sleep; in these respects resembling tea and coffee. It is asserted to support the strength for a considerable time in the absence of food; but it does not supply the place of nutriment, and probably, in this respect also, acts like the two substances referred to. The Indians, while chewing it, pass whole days in travelling or working without food; but they nevertheless eat freely in the evenings. Weddell states that persons, unused to it, are liable to unpleasant effects from its abuse; and he has known instances of hallucinations apparently resulting from this cause. The natives chew it with it some alkaline substance, as the ashes of certain plants, or lime. (Weddell, Voyage dans le Nord de la Bolivie.) In large quantities, it is said to produce a general excitation of the circulatory and nervous systems, im-
Euphorbium,—Ferricyanide of Potassium.  

PART III.

parting increased vigour to the muscles as well as to the intellect, with an indescribable feeling of satisfaction, amounting altogether sometimes to a species of delirium; and what is most singular, if true, this state of exaltation is asserted not to be followed by any feelings of languor or depression. (Mantegazza, N. Am. Med.-Char. Rev., March, 1860, p. 540.) A medium dose is from three to four draughts, taken in infusion. For the result of experiments on the physiological action of coca by M. Reis, see Ann. de Thérap. (1864, p. 118). W.

EUPHORBIUM. This was contained in the materia medica catalogue of the late Edinburgh Pharmacopoeia; but, having been omitted in the British, it is no longer officinal. It is the concrete resinous juice of one or more species of Euphorbia; but its precise source is uncertain. It has been ascribed to E. officinarum, growing in the north of Africa and at the Cape of Good Hope. E. Canariensis, a native of the Canary Islands and Western Africa, and E. antiquorum, inhabiting Egypt, Arabia, and the East Indies, and supposed to be the plant from which the ancient authors derived this resinous product. These species of Euphorbia bear some resemblance in form to the Cactus, having leafless, jointed, angular stems, divided into branches of a similar structure, and furnished with double prickles at the angles. When wounded, they yield an acrid milky juice, which concretes on the surface, and, being removed, constitutes the euphorbium of commerce.

This occurs in the shape of tears, or in oblong or roundish masses, about the size of a pea or larger, often forked, and perforated with one or two small conical holes, produced by the prickles of the plant, around which the juice has concreted, and which sometimes remain in the holes. The masses are occasionally large and mixed with impurities. The surface is dull and smooth, bearing some resemblance to that of tragacanth; the consistence somewhat friable; the colour light yellowish or reddish; the odour scarcely perceptible; the taste at first slight, but afterwards excessively acrid and burning. The colour of the powder is yellowish. The sp. gr. of euphorbium is 1-124. Triturated with water it renders the liquid milky, and is partially dissolved. Alcohol dissolves a larger portion, forming a yellowish tincture, which becomes milky on the addition of water. Its constituents, according to Pelletier, are resin, wax, malate of lime, malate of potassa, lignin, bassorin, volatile oil, and water. Brandes found caoutchouc. It contains no soluble gum. The proportions of the ingredients are variously stated by different chemists, and probably vary in different specimens. The most abundant is resin, and the remainder consists chiefly of wax and malate of lime. The resin is excessively acrid, is soluble in alcohol, and, when exposed to heat, melts, takes fire, and burns with a brilliant flame, diffusing an agreeable odour.

Medicinal Properties and Uses. Euphorbium taken internally is emetic and cathartic, often acting with great violence, and in large doses producing severe gastric pain, excessive heat in the throat, and symptoms of great prostration. In consequence of the severity of its action, its internal use has been entirely abandoned. Applied to the mucous membrane of the nostrils, it excites violent irritation, attended with incessant sneezing and sometimes bloody discharges. They who powder it are under the necessity of guarding their eyes, nostrils, and mouth against the fine dust which rises. Largely diluted with wheat flour or starch, it may be used as an errhine in amaurosis, deafness, and other obstinate affections of the head. Externally applied, it inflames the skin, often producing vesication; and on the continent of Europe is sometimes used as an ingredient of epistemic preparations. It is employed in veterinary practice, with a view to its vesicating power.

EUPHRASIA OFFICINALIS. Eyebright. A small annual plant, common to Europe and the United States, without odour, and of a bitterish, astringent taste. It was formerly used in various complaints, and among the rest in disorders of the eyes, in which it was thought to be very efficacious, and in the treatment of which it is still popular in some countries. The probability is that it is nearly inert.

FERRICYANIDE OF POTASSIUM. Red Prussiate of Potassa. This is formed by passing a current of chlorine through a solution of ferrocyanide of potassium, until the liquid ceases to form a precipitate with a solution of sesquichloride of iron, a proof that the whole of the ferrocyanide has been converted into the ferricyanide. The solution, by due evaporation, yields the compound in question. It may also be prepared, in the dry way, by agitating chlorine with the finely powdered ferrocyanide, as long as it is absorbed. The theory of the formation of this compound is that one eq. of chlorine withdraws from two eqs. of the ferrocyanide, one eq. of potassium, forming chloride of potassium which remains in the mother-water. The reaction is explained by the following equation: 2(K,Cfy) and CI = K3Cfy2 and KCl. The radical ferricyanogen is supposed to be formed by the coalescence of two eqs. of ferrocyanogen, and is represented by the symbol, Cfy. Accordingly, the formula of ferricyanide of potassium is K3Cfy. This salt, discovered by Gmelin, is in beautiful deep hyacinth-red anhydrous crystals, which are soluble in four parts of water. Its solution forms a delicate test of the salts of protoxide of iron, with which it produces a blue precipitate; but with the salts of the sesquioxide, it only strikes a green or brown colour. Ferricyanide of potassium is directed by the U.S. Pharmacopoeia, in
conjunction with sulphate of protoxide of iron, as a test of the chlorine strength of chlorinated lime. (See page 187.) It is used in dyeing and calico-printing.

FERROCYANIDE OF ZINC. Zinci Ferrocyanidum. Ferrocyanuret of Zinc. Formed by double decomposition between hot solutions of ferrocyanide of potassium (ferroprussiate of potassium) and sulphate of zinc. It is thrown down as a white powder. It has similar medical properties to those of the cyanide, and is used in the same diseases. The dose is from one to four grains, given in pill. (See Cyanide of Zinc.)

FLAVOURING EXTRACTS. Under this name, preparations from various aromatics are considerably used for culinary purposes. They are in the liquid form, and are generally alcoholic solutions of the rapid and odorous principles of substances having an agreeable flavour, such as orange peel, bitter almonds, roses, cinnamon, nance, ginger, and celery. Formulas for their preparation, given by Prof. Procter, may be found in the Am. Journ. of Pharm. for May, 1856, p. 215.

FRAXINUS EXCELSIOR. Common European Ash. It has been stated, in the first part of this work, that, in the south of Europe, this tree yields manna by incisions in its trunk. In this place, however, it is noticed only in reference to its bark and leaves. The bark is bitter and astringent, and, before the introduction of cinchona into use, was employed in the treatment of intermittent fever; but since has fallen into neglect. Keller believed that he had found in the bark a peculiar crystallizable organic alkali, which Buchner denominated fraxinin; but Rochleder and Schwartz have since shown that the crystals, formed along with the bitter substance obtained by the process of Keller, were nothing but mannite. (Pharm. Cent. Blatt, May, 1853, p. 312.) Since that period, however, a crystallizable bitter principle has been discovered by Prince Salms-Horsman, which has been named fraxin. It is obtained by precipitating the decoction with acetate of lead, washing the precipitate, decomposing it by sulphuretted hydrogen, and concentrating the solution, which deposits the fraxin in needle shaped crystals. These are four-sided prisms, shining, white with a tinge of yellow, feebly bitter and astringent, inodorous, soluble with difficulty in cold but readily in hot water. The concentrated warm solution has an acid reaction. When much diluted, it exhibits a clear blue fluorescence by daylight, especially if a trace of ammonia is present. Alkalies, alkaline earths, and the carbonates colour it yellow; and chloride of iron first colours it green, and then throws down a yellow precipitate. (Chem. Cent. Blatt, Juli 8, 1857, p. 452.) The leaves have been at different times recommended as an antidote to the poison of serpents, and as a remedy in scrofula. Within a few years they have been introduced into use in Germany in the treatment of gout and rheumatism, in which they have acquired considerable reputation. Drs. Pouget and Peyraud, of France, have spoken in the highest terms of their efficacy in these diseases; and, upon the authority of the former, it is stated that they have been used for forty years by the peasants of Auvergne as a specific in gout. M. Garot has shown that they contain 16 per cent. of malate of lime, to which it is thought their anti-arthritic virtues may be ascribed. (Journ. de Pharm., 2e sér., xxiv. 311.) By some authors the leaves are said to be purgative, which is, however, contradicted by Drs. Pouget and Peyraud. An ounce may be infused in half a pint of boiling water, and taken three times during the day. (See Am. Journ. of Med. Sci., N.S., xxv. 492.)

FRENCH CHALK. A variety of indurated t alc. It is compact, unctuous to the touch, of a greenish colour, glossy, somewhat translucent, soft and easily scratched, and leaves a silvery line when drawn over paper. It is used chiefly for marking cloth, &c., and for extracting grease spots.

FRUIT ESSE NCES, ARTIFICIAL. Several of the compound ethers have been found to possess the odour and flavour of certain fruits, a property which has led to their employment as flavouring materials for confectionery and desserts, under the name of fruit essences. The simple ethers, present in these compounds, so far as they have become of commercial importance, are common ether or oxide of ethyl, which should be called ethyl ether, and oxide of amyl or amylic ether. Each of these ethers possesses basic properties, and has its alcohol; common or ethyllic ether corresponding to common or ethyllic alcohol, and amyllic ether to amyllic alcohol or fusel oil. These alcohols are hydrated oxides of ethyl and amyl respectively. (See Alcohol Amylicum, p. 78, and Alcohol, p. 73.)

Butyrate of Ethyl Ether. Butyric Ether. (C₂H₅O₂C₂H₄O₂) This ether is readily prepared by mixing 100 parts of butyric acid with 100 of alcohol, and 50 of concentrated sulphuric acid, and agitating the mixture for a short time. The ether then forms a layer on the surface, and may be purified by washing it with water, and subjecting it to the action of chloride of calcium. Butylic ether is sparingly soluble in water, and fairly soluble in alcohol, and boils at 280°. It is said to be much used to communicate a pine-apple flavour to rum. Dissolved in 8 or 10 parts of alcohol it forms the pine-apple essence. From 20 to 25 drops of this essence, added to a pound of sugar containing a little citric acid, imparts to the mixture a strong taste of pine-apple. Butyric acid is formed during what is called the butyric fermentation, which usually consumes two or three months before it is completed, and
which is preceded by the lactic fermentation. To prepare it a solution of grape sugar is mixed with half its weight of chalk, and with about one-tenth of its weight of cheese to act as a ferment, and the whole is kept at the temperature of 96°. The sugar is first transformed into a viscous substance, and afterwards into lactic acid, which is gradually converted into butyric acid, with the disengagement of hydrogen and carboxic acid. At the end of the fermentation, the liquid contains principally a mixture of butyrate and lactate of lime, from which the butyric acid may be obtained by precipitating the lime as a carbonate by carbonate of soda, and decomposing the resulting butyrate of soda with sulphuric acid. Butyric acid is a colourless liquid, having a very disagreeable odour and a rancid taste. It dissolves in all proportions in water and alcohol, boils at 827°, and has the density 0·963. It is a hydrated acid, having the formula C₆H₁₂O₇·HO.

Pelargonic of Ethyl Ether. Pelargonic Ether. (C₆H₁₀O₊·C₅H₅O₆.) A preliminary step in forming this ether is to prepare the pelargonic acid. This is most conveniently obtained, according to Dr. R. Wagner, by the action of nitric acid on oil of rue. Treat the oil with double its weight of very dilute nitric acid, and heat the mixture until it begins to boil. Two layers are formed in the liquid; the upper one being brownish, and the lower consisting of the products of the oxidation of the oil, with the excess of nitric acid. The lower layer, having been separated, is freed from the greater part of the nitric acid by evaporation in a chloride of zinc bath, and then filtered. The filtrate is a solution of pelargonic acid, and may be converted into pelargonic ether by a prolonged digestion, at a gentle heat, with alcohol. The ether, as thus prepared, has the agreeable odour of quince, and, when dissolved in alcohol in due proportion, forms the quince essence. (See Am. Journ. of Pharm., July, 1858, p. 820.) Pure pelargonic ether (enanethic ether) is a colourless liquid, having a peculiar, vinous, stupefying odour, and a taste, at first slight, but afterwards acid. Its sp. gr. is 0·872, and boiling point, when constant, 433°. (Delfs.) It is insoluble in water, but dissolves readily in alcohol and ether. Pelargonic acid, so called from its having been first obtained from Pelargonium roseum, or rose geranium, is a hydrated acid, and has the formula C₆H₁₂O₇·HO. Delfs's analysis of enanethic acid gives it the same composition; and, accordingly, he considers the two acids as undoubtedly identical. (Chem. Gaz., April 15, 1852, p. 144.) Gregory adheres to the old formula for enanethic acid, C₆H₁₃O₇·HO.

Acetate of Amylic Ether. (C₆H₁₀O₆·C₅H₅O₆.) This is prepared by distilling a mixture of one part of amyl alcohol (fusel oil), two of acetate of potassa, and one of concentrated sulphuric acid. The distilled liquid is purified from free acid by washing with a weak alkaline solution, and from water by distillation from chloride of calcium. It is a colourless, limpid liquid, lighter than water, boiling at 272°, insoluble in water, but soluble in alcohol. It possesses the odour, in a remarkable degree, of the Jargonelle pear, and is manufactured on a large scale for flavouring syrups and confectionery. An alcoholic solution of this ether forms the Jargonelle pear essence. Fifteen parts of acetate of amyl ether, with half a part of acetic ether, dissolved in 100 parts of alcohol, form what may be called the bergamot pear essence, which, when employed to flavour sugar acidulated with a little citric acid, imparts the odour of the bergamot pear, and a fruity, refreshing taste. Acetate of amyl ether, mixed with butyric ether, forms another fruity compound, which recalls the odour of the banana, and forms, in alcoholic solution, the banana essence.

Valerianate of Amylic Ether. (C₆H₁₁O₆·C₅H₅O₆.) This is made by carefully mixing four parts of pure amyl alcohol (fusel oil) with four of sulphuric acid, and adding the mixture, when cold, to five parts of valerianic acid. The whole is warmed for a few minutes in a water-bath, and then mixed with a little water, which causes the ether to separate. Lastly, it is purified by washing it with water and a weak solution of carbonate of soda. An alcoholic solution of this ether, in the proportion of one part to six or eight of alcohol, forms a flavouring liquid under the name of apple essence. For the mode of obtaining valerianic acid, see Acidum Valerianicum (page 942).

It is thus perceived that the bases of the fruit essences are certain ethereal compounds of organic acids with the oxides of ethyl and amyl. Besides the essences here described, there are found in commerce the strawberry, raspberry, apricot, greengage, mulberry, and black currant essences, all of which may be viewed as various mixtures of the ethers of the ethyl and amyl series, modified by the addition of pure nitrous ether, tincture of orris, vanilla, volatile oils, &c., to bring about a resemblance to the fruit, the odour and taste of which it is the object to imitate. In making these essences, it is important that the materials should be pure, especially the fusel oil and alcohol. The alcohol, used as a solvent, should be rectified and deodorized.

These fruit essences are extensively employed for flavouring ices, jellies, lozenges, and drops, and for making fruit syrups and effervescent beverages. They are manufactured on a large scale by Messrs. Mander, Weaver & Co., of Wolverhampton, England; and the more useful ones are prepared by Messrs. Powers & Weightman, of Philadelphia.

FUCUS VESICULOSUS. Sea-wrack. Bladder-wrack. This was omitted as an official in the edition of the Dublin Pharmacopoeia of 1850. It belongs to Cryptogamia Algae in the
sexual system, and to the natural order Algaceae. The following is the generic character.

**Fucus** - *Vegetable* smooth, hollow, with villose hairs within, interwoven. **FEMALE.** Vegetles smooth, filled with jelly, sprinkled with immersed grains, prominent at tip. **Seeds solitary.**

This sea-weed is perennial, with the frond or leaf flat, smooth and glossy, from one to four feet long, from half an inch to an inch and a half broad, furnished with a midrib throughout its length, dichotomous, entire upon the margin, and of a dark olive-green colour. Small spherical vesicles, filled with air, are immersed in the frond near the midrib. The fruit consists of roundish, compressed receptacles, at the ends of the branches, filled with a clear tasteless mucus. The plant grows upon the shores of Europe and of this continent, attaching itself to the rocks by its expanded woody root. On the coasts of Scotland and France, it is much used in the preparation of kelp. It is also employed as a manure, and is mixed with the fodder of cattle. It has a peculiar odour, and a nauseous saline taste. Several chemists have undertaken its analysis, but the results are not satisfactory. It contains much soda in saline combination, and iodine, according to Gaultier de Claibury, in the state of iodide of potassium. These ingredients remain in its ashes, and in the charcoal resulting from its exposure to heat in close vessels.

This charcoal, which is sometimes called *Ethiops vegetabilis* or vegetable *ethiops*, has long had the reputation of a deobstruent, and been given in goitre and scrophulous swellings. Its virtues were formerly ascribed chiefly to carbonate of soda, in which it abounds; but, since the discovery of the medical properties of iodine, this has been considered as its most active ingredient. The mucus contained in the vesicles was applied externally, with advantage, by Dr. Russell, as a resolvent in scrophulous tumours. M. Duchesne Duparre, having given a trial to this fucus in invertebrate poriiasm, in which it had considerable reputation as a remedy, found it of little value; but he observed an unexpected effect, that of diminishing fat, without in other respects injuring the health; and was thus induced to try it as a remedy for morbid obesity. His anticipations of its efficacy in this affection were not disappointed. He employs the whole plant, either in substance in the form of pill, in decoction, or in extract. It is not till two or three weeks after beginning with the remedy that its effects in diminishing the obesity begin to be perceived, and one of the first signs of its favourable action in this respect is the increase of the urine, and the appearance of a black pellicle on its surface. Dr. Godsfrey tried the experiment on himself with satisfactory results, confirming the statements of M. Duchesne. (Pharm. Journ., Juillet, 1862. p. 65.) M. Dannecey prepares the extract from the plant, collected at the period of fruitification about the end of June, in the neighbourhood of Bordeaux, and rapidly dried in the sun. This mode of desiccation is important, as, when dried by artificial heat, the plant never becomes friable, and always retains its hygroscopic qualities. When sufficiently dry to be friable, it treats it, in the state of coarse powder, for three days, with four times its weight of alcohol of 80°, expresses at the end of this time, and subjects the residue twice successively to a similar treatment with alcohol of 54°. The tinctures are then mixed, the alcohol distilled off, and the remainder evaporated to the consistency of an extract. Of this extract, which is one-fifteenth of the plant, three pills, each containing 25 centigrammes (513 grains), may be taken daily in the beginning, and increased gradually to twenty-four pills, a quantity which has often been attained without the slightest derangement of the stomach. The commencing dose would be about equivalent to twenty grains of the powder three times a day. (Journ. de Pharm., Nov. 1862. p. 434.) A syrup may be readily prepared by dissolving the extract in a little diluted alcohol, and mixing this with syrup, in such proportion that a teaspoonful of the syrup shall contain a dose of the extract.

Other species of *Fucus* are in all probability possessed of similar properties. Many of them contain a gelatinous matter, and a sweet principle analogous to mannite; and some are used as food in times of scarcity. Large quantities of a sea-weed, named in the East *agar-agar*, are gathered on the rocky coasts of the East India Islands, and sent to China, where it is valued for making jellies, and as a size for stiffening silks. The *Ceylon moss* is a delicate fucus (*Gigartina lichenesoides*), growing on the coast of Ceylon, where it is gathered by the natives. It abounds in starch and vegetable jelly, which render it applicable to the same purposes as the carrageen or Irish moss. (Pharm. Journ., xiii. 365.) *F. Helminthocoron* (*Gigartina Helmintochoron* of Greville) has some reputation in Europe as an anthelmintic, and is said also to be sebrefuge. It is an ingredient in the mixture of marine plants sold in Europe under the name of *Corseian moss* or *helminthocoron*. This is used in decoction, from four to six drachms being boiled in a pint of water, and a wineglassful given three times a day.

**FULIGOKALI.** This preparation, proposed by M. Deschamps, is formed by boiling for an hour, 20 parts of caustic potassa, and 100 of shining coal, in powder, in a sufficient quantity of water. The solution, when cold, is diluted, filtered, and evaporated to dryness. Fuligokali is in the form of a black powder, or of scales, very soluble in water, and having an empyreumatic odour and mild alkaline taste. It is used in the same affections as *anthraokali*. The dose is two or three grains, repeated several times a day. An ointment, containing from 16 to 32 grains to the ounce of lard, was found by Dr. Gibert, of
Paris, to be deterrent, resolvent, and gently stimulant. (See a paper by A. Duhamel, in the Am. Journ. of Pharm., xiv. 284.)

FUMARIA OFFICINALIS. Fumitory. A small annual European plant, naturalized in this country, growing in cultivated grounds, and flowering from May to August. It was formerly considerably employed as a medicine, and is still used in Europe. The leaves are the official part. They are inodorous, have a bitter saline taste, and are very succulent, yielding by expression a juice which has the sensible and medicinal properties of the plant. An extract, prepared by evaporating the expressed juice or a decoction of the leaves, throws out upon its surface a copious saline efflorescence. The plant, indeed, abounds in saline substances, and to these, in connection with its bitter extractive, its medical virtues have been ascribed. Recently, however, M. Hannon, of Belgium, has ascertained the presence in fumitory of an alkaloid, called fumarin (fumarina), to which he ascribes the effects of the plant. He obtained it by treating the pulp of the leaves with concentrated acetic acid, with the aid of heat, filtering, evaporating the liquid, treating the extract with boiling alcohol, filtering the alcoholic solution, and, finally, decolorizing, and evaporating so that crystals might form. The acetate thus procured was decomposed by the alkalies, and yielded the fumarina. Fumitory has been considered gently tonic, alterative, and, in large doses, laxative and diuretic. But M. Hannon considers it mainly sedative, and states that its prolonged use diminishes plethora, and may even produce anæmia. He has found fumarina, in the dose of about one-third or one-fourth of a grain, to be moderately excitant; in that of three grains, to be at first irritant and afterwards sedative. (Ann. de Thérap., 1854, p. 78.) Both in ancient and modern times fumitory has been esteemed a valuable remedy in visceral obstructions, particularly those of the liver, in scorbatic affections, and in various troublesome eruptive diseases. Cullen speaks favourably of it in these last complaints. He gave two ounces of the expressed juice twice a day. Others have prescribed it in much larger quantities. The leaves either fresh or dried may be used in decoction, without precise limitation as regards the dose. The inspissated juice, and an extract of the dried leaves have also been employed.

FUSTIC. A yellow dye-wood, obtained from Morus tinctoria (Broussonetia tinctoria, Kunth), a tree growing in the West Indies and South America. It is not used in medicine or pharmacy. According to Bancroft, two different woods bear in England the name of fustic, one the product of the tree just mentioned, distinguished as old fustic, probably from the greater magnitude of the billets in which it is imported; the other derived from the Rhús Cotinus or Venice sumach, and called young fustic. The wood of M. tinctoria owes its colouring properties to three principles, which have been isolated by R. Wagner; one denominated morin, and the other moritannic acid, from its resemblance to tannin. (See Chem. Gaz., ix. 1, 21, and 241.)

GALANGAL. Galanga. Two varieties are described by authors, the galanga major and galanga minor, or large and small galangal. They are considered by some as the roots of different plants; but there is reason to believe that they are both derived from Maranta Galanga of Linn. (Alpína Galanga of Wild.), and that they differ in consequence of the different stages of growth at which they are collected. They are brought from the East Indies. The larger variety is cylindrical, three or four inches long, as thick as the thumb or thicker, often forked, reddish-brown externally, slightly striated longitudinally, marked with whitish circular rings, orange-brown internally, rather hard and fibrous, difficultly pulverizable, of an agreeable aromatic odour, and a pungent, hot, spicy, permanent taste. The small galangal resembles the preceding in shape, but is smaller, not exceeding the little finger in thickness, of a darker colour, and of a stronger taste and smell. According to Morin, galangal contains a volatile oil, an acrid resin, extractive, gum, bassorin, and lignin. A. Vogel, jun., found also starch and fixed oil. (Pharm. Cent. Blatt, 1844, p. 158.) R. Brandes discovered a peculiar crystallizable substance called kempferid. (Annal. der Pharm., xxxii. 311.) The active principles are the volatile oil and acrid resin. The medical effects of galangal are those of a stimulating aromatic. It was known to the ancient Greeks and Arabians, and formerly entered into numerous compound preparations. At present it is seldom employed. Its dose is from fifteen to thirty grains in substance, and twice as much in infusion.

GALEGA OFFICINALIS. Goat's Rue. A perennial herb, growing in the south of Europe, and sometimes cultivated in gardens. It is without smell unless bruised, when it emits a disagreeable odour. Its taste is unpleasantly bitter and somewhat rough, and when chewed it stains the saliva yellowish-brown. In former times it was much employed as a remedy in malignant fevers, the plague, the bites of serpents, worms, &c.; but it has fallen into merited neglect. The roots of Galega Virginiana, a native of the United States, are said to be diaphoretic and powerfully anthelmintic. They are given in decoction.

GALIUM APARINE. Cleavers. Goose-grass. This is an annual, succulent plant, common to Europe and the United States, growing in cultivated grounds, and along fences and hedges. It is inodorous, and has a bitterish, herbaceous, somewhat acid taste. Analyzed
by Schwartz, it was found, besides chlorophyll, starch, and other principles common to all plants, to contain three distinct acids, viz., a variety of tannic acid, which he names \textit{galitannic acid}, citric acid, and a peculiar acid, previously discovered by Schwartz and Rochleder, and named \textit{rubichloric acid}. (\textit{Pharm. Journ.}, xii. 190.) The expressed juice is said to be aperient, diuretic, and antiscorbutic, and has been used in dropsy, congestion of the spleen, scrofula, and scorbutive eruptions. In the last complaint it has been thought peculiarly useful. Three ounces of the juice may be taken twice a day. Dr. Winn, of Truro, Cornwall, has called the attention of the profession to this medicine. Several persons in his neighbourhood had been cured of lepra by a decoction of the plant; and he had himself employed it with great advantage not only in this but other cutaneous diseases. At first he gave it in the form of decoction made by boiling a handful of the recent herb in a quart of water for twenty minutes, of which a tumblerful was given three times a day; but he afterwards preferred the inspissated juice, in the form of a fluid extract, of which \(\frac{1}{2}\) should represent half a pint of the decoction. (\textit{London Med. Times and Gaz.}, Feb. 1854, page 144.) The fresh herb, in the form of ointment or decoction, has been applied externally to scrofulous swellings with supposed advantage.

**GALIUM VERUM. Yellow Ladies' Bedstraw. Cheese rennet.** This species of Galium is perennial, and a native of Europe. The flowers, which are yellow, have a peculiar, agreeable odour, and have been given in nervous affections, with a view to their supposed antispasmodic powers. The herb is inodorous, but has an astringent, acidulous, bitterish taste. The property of coagulating milk was formerly ascribed to it, but is certainly not constant, as the experiment has been frequently tried without success. The bruised plant is sometimes used to colour cheese yellow, being introduced into the milk before coagulation. It is also used for dyeing yellow. The roots of this and of most other species dye red; and the plant, eaten by animals, colours the bones like madder. This plant was analyzed by Schwartz, and found to contain the same principles as \textit{G. Aparine}, mentioned above. It was formerly highly esteemed as a remedy in epilepsy and hysteria, and was applied externally in cutaneous eruptions. It may be employed in the form either of the recently expressed juice, or of a decoction prepared from the fresh plant. Its medical properties, however, are feeble. Testimony has recently been given, in France, to the special efficacy of \textit{Galium palustris} in epilepsy. (\textit{Ann. de Thérap.}, 1863, p. 77.)

Of the American species, \textit{G. tinctorium} is closely allied in properties to \textit{G. verum}. It is said to be useful in cutaneous diseases, and the root is employed by the Indians for staining their feathers and other ornaments red.

**GARDENIA GRANDIFLORA.** A Chinese tree, the fruit of which is employed in dyeing the yellow robes of the mandarins. It has acquired some additional interest from a recent chemical examination of the fruit by Lorenz Mayer, in the laboratory of Rochleder, the result of which was the discovery of a colouring substance, which proved to be identical with that of saffron, and to which, therefore, the name of \textit{crocin} was given. In powder, it is of a bright-red colour, and is soluble in water and alcohol. By treatment with muriatic acid, it yields another colouring substance called \textit{crocein}, which is a true dye-stuff. (\textit{Chem. Gaz.}, Sept. 1, 1858, p. 331.) The fruit of another species, \textit{G. campanulata}, growing in the forests of Chittagong, in India, is said to be used by the natives as a cathartic and anthelmintic. (Lindley, \textit{Flor. Med.}, p. 434.)

**GENISTA TINCTORIA. Dyers' Broom. Dyers' Weed. Green Weed.** A low shrub, growing wild in Europe, and sometimes cultivated in this country in gardens. The flowering tops of the plant are employed to dye yellow, whence its name was derived. Both these and the seeds have been used in medicine. They are said to be purgative and even emetic, especially the seeds, which were formerly given as a cathartic in the dose of a drachm and a half. By some authors they are said to be diuretic, and to be useful in dropsy. The plant has been long used as a preventive of hydrophobia by the peasants of Podolia, the Ukraine, and other provinces of Russia. They employ it in the form of strong decoction, both internally and locally, in connection with \textit{Rhus coriaria}, and persevere with it for six weeks. The trials made with it in other parts of Europe have failed.

**GERANIUM ROBERTIANUM. Herb Robert.** This species of Geranium grows wild both in Europe and the United States, but is rare in this country; and Pursh states that the American plant is destitute of the heavy smell by which the European is so well known, though the two agree in all other respects. The herb has a disagreeable, bitterish, astringent taste, and imparts its virtues to boiling water. It has been used internally in intermittent fever, consumption, hemorrhages, nephritic complaints, jaundice, &c., has been employed as a gargle in affections of the throat, and has been applied externally as a resolvent to swollen breasts and other tumours.

**GLASS OF ANTIMONY. \textit{Vitrum Antimonii.}** This is prepared from the tersulphuret of antimony by a partial roasting and subsequent fusion. The tersulphuret, reduced to coarse powder, is strewed upon a shallow, unglazed earthen vessel, and heated gently and slowly, being continually stirred to prevent it from running into lumps. White vapours of sulphur-
ous acid arise; and, when these cease, the heat is increased a little to reproduce them. The roasting is continued in this manner until, at a red heat, no more vapours are given off. The matter is then melted in a crucible with an intense heat, and kept in a state of fusion until it assumes the appearance of melted glass, when it is poured out on a heated brass plate. In this process, part of the sulphur of the tersulphuret is driven off by the roasting; while the portion of antimony which loses its sulphur becomes tersulphurized. The roasted matter, therefore, consists of tersulphuret of antimony and undecomposed tersulphuret; and these, by uniting during the fusion, form the glass. Glass of antimony is in thin irregu-
lar pieces, exhibiting a vitreous fracture, and having a metallic steel-gray lustre. When well prepared it is transparent and red, and, upon being held between the eye and the light, ap-
ppears of a rich orange-red or garnet colour; but if of inferior quality it is black and opaque. It is hard and brittle, and rings when struck with a hard substance. It is insoluble in water, but soluble in acids and cream of tartar, with the exception of a few red floculi. Its essen-
tial constituents are the tersulphuret and tersulphurized, united in variable proportions. When of good quality it consists of about eight parts of tersulphuret to one of tersulphurized. It usually contains about 5 per cent. of silica, and three of sesquioxide of iron, which are derived from the crucible, and to the former of which the vitrification of the product is owing. When good it is dissolved, with the exception of a few red floculi, in strong muriatic acid. An excess of the silica is shown by the acid leaving a gelatinous residue, and the iron may be detected by ferrocyanide of potassium, and its amount judged of by the bulk of the precipitate and the depth of its blue colour. Sometimes glass of lead is sold for glass of antimony, a fraud readily detected by the difference between the two substances in specific gravity; glass of lead having a density of nearly seven, while that of glass of antimony is not quite five.

Medical Properties, &c. Glass of antimony is an active antimonial; but, owing to its variable composition and unequal operation, it is at present very seldom used. When the levigated powder is mixed with one-eighth of its weight of melted yellow wax, and the mixture roasted over a slow fire, with constant stirring, until it ceases to exhalc vapours, a coal-like pulverizable mass is formed, which is the cerated glass of antimony, a prepara-
tion formerly included in the Edinburgh Pharmacopoeia.

GLOBULARIA ALYPUM. Wild Senna of Europe. This is a small shrub, growing on the European shores of the Mediterranean, the leaves of which have been occasionally used as a cathartic since the middle ages. Dr. Gustave Planchon, of Montpellier, France, in an essay on the plants of this genus, published in 1859, states that the leaves of this spec-
est are a mild and efficient cathartic, without the griping properties of senna, and with-
out leaving behind a tendency to constipate like rhubarb, which, however, it resembles in tonic power. One ounce is given for a dose in decoction. It is unknown in this country. (See Pharm. Journ., xvi. 426.)

GLECHOMA HEDERACEA. Nepeta Glechoma. Ground-ivy. A small perennial herb, indigenous in Europe and the United States, and growing in shady grassy places, as in orchards and along fences and hedges. It belongs to the family of labiate plants, and shares their general properties. The herb was formerly officinal, and still enjoys some credit as a domestic remedy. It has a peculiar disagreeable odour, and a bitterish, somewhat aroma-
tic taste, and imparts its properties to boiling water. It is said to be gently stimulant and tonic, with, perhaps, a peculiar direction to the lungs and kidneys. It has also been considered aperient. It has been most used in chronic affections of the pulmonary and urinarv organs, and at one time had considerable reputation as a remedy in consumption. It has also been employed as a vulnerary and errhine. The usual form for exhibition was that of infusion, of which a dose was given containing the virtues of half a drachm or a drachm of the herb.

GLUE. An impure form of gelatin, obtained from various animal substances by boiling them in water, straining the solution, and evaporating it till upon cooling it assumes the consistence of jelly. The soft mass which results is then divided into thin slices, which are dried in the open air. Glue, when of good quality, is hard and brittle, of a colour varying from light-yellow to brown, and equally transparent throughout. It softens and swells very much in cold water, without dissolving; but is readily dissolved by hot water. It is employed chiefly for cementing pieces of wood, being generally too impure for the purpose of a test, or as an article of food. An elastic and impermeable preparation of glue, useful for various purposes in the arts and in medicine, may be made by dissolving glue in water by means of a water-bath, concentrating the solution, then adding a weight of glycerin nearly equal to that of the glue employed, thoroughly mixing, evaporating the residue of the water, and finally pouring into moulds, or on a marble slab. It is especially applicable to the preparation of artificial anatomical specimens. (Journ. de Pharm., Jan. 1857, p. 28.)

Capsules of Gelatin. Glue has with a few years been applied to an important practical purpose in pharmacy. Certain medicines are so offensive to the taste, and consequently so apt to sickness the stomach, that it is highly desirable to administer them in such a way
as to prevent their contact with the tongue and palate. This object is fully accomplished, so far as regards many disagreeable liquid medicines, by the use of the capsules of gelatin, invented by M. Dublanc, of Paris. These are prepared from the purest glue in the following manner. Small pouches made of fine skin, of an oval form, are attached by a waxed thread to the smaller extremity of a hollow elongated metallic cone, which is bent towards its point, and has its base closed by a cover, which is screwed so as to make the instrument air-tight. Into this conical tube sufficient mercury is poured to fill the pouch, which, thus distended, is dipped into a concentrated solution, made by heating six parts of pure glue with one of sweetened water, and is afterwards exposed to heat in a vertical position, so as to dry the layer of gelatin which it has received. In the same manner a second coating may be given, and the process again repeated till a sufficient thickness has been obtained. The cone being then reversed, the mercury flows out of the pouch, which collapses, and allows the capsule of gelatin to be removed. Into this the medicine may now be introduced, care being taken to avoid any contact with the outer surface of the capsule. The opening is next to be closed by means of a thin lamina of gelatin previously softened by steam; and a solution of the same substance should be applied to the edges by means of a camel's hair pencil. Another mode of preparing the capsules is as follows. Take a cylinder of iron or hard wood, four lines in diameter and a few inches long, and smoothly rounded at one end. Dip half an inch of this end first into a saturated warm alcoholic solution of soap, and afterwards, when the soap has concreted upon the surface, into a concentrated hot solution of gelatin, and repeat the latter immersion once or oftener, if it be desired to have a firm capsule. When the glue has concreted, remove the capsule. A top for it may be made in the same way, and, after the body has been filled with the liquid to be given, is to be applied, and secured by rubbing a camel's hair pencil moistened with hot water over the line of junction. (Med. Exam., N.S., i. 441.) M. Motheé considers the following plan of preparing the capsules the most convenient. He has a number of assorted 'copper olives' prepared, covers their surface with a layer of something to prevent oxidation, immerse them in a sweetened and aromatized concentrated solution of gelatin, then places them vertically on boards to cool, and before complete desiccation removes the capsules, places them on sieves, and dries them by a stove-heat. (Journ. de Pharm., xvii. 294.) Mr. Redwood gives the following process, which is a modification of the second method above described. A polished bulb of iron, ivory, or bone, of the size and shape of the capsules required, and connected by a slender rod with a handle, is first greased by rubbing with an oiled cloth, and then dipped into a solution of gelatin made as above directed. Upon being withdrawn, it is held for a short time so as to allow the excess of the solution to run off, and then fixed with the handle in a board, the coated bulb being upward, until the coating becomes cold and firm. The capsule is now removed by the fingers, and further dried by exposure on a tray. A number of capsules having been prepared, they are placed each in a small cell upon a board, with their mouths upward; and the liquid they are to contain is introduced by means of a syringe with a fine point. Their mouths are then closed with a drop of the solution of gelatin applied by means of a camel's hair pencil, which is afterwards strengthened by an additional coating, given by dipping the mouth of the capsule into the solution diluted with a little water. (Redwood's Supplement, p. 664.) The capsules may be made of such a capacity as to contain from ten to fifteen grains of copaiba.

W. GNAFHALIUM MARGARITACEUM. Oxidweed. Life-everlasting. An indigenous herbaceous perennial, growing in fields and woods, and flowering in August. The herb of this species and of G. polycephalum, or sweet-scented life-everlasting, is sometimes used, in the form of tea, by the country people, in diseases of the chest and of the bowels, and in hemorrhagic affections, and externally, in the way of fomentation, in bruises, languid tumours, and other local complaints; but it probably possesses little medical virtue. Sheepey says that it is anodyne. In Europe different species of Gnaphalium are also occasionally employed for similar purposes.

W. GOLD. Aurum. The preparations of this metal were introduced to the notice of physicians by Dr. Chrestien, of Montpellier, in 1810. They are employed both internally, and by friction on the tongue and gums. The principal affections in which they have been recommended are secondary syphilis, syphilitic ulcerations, scrofula, and invertebrate eruptions, particularly those of a leprous character. The chief preparations which have been employed, up to the present time, are metallic gold in a leaf divided, the oxide of gold, the chloride (tecthloride), the iodide, the double chloride of gold and sodium, the chloroaurate of ammonia (a compound of tetrachloride of gold and muriate of ammonia), and the cyanide (tcecyanide) of gold. Gold in powder may be obtained by rubbing up gold-leaf with 10 or 12 times its weight of sulphate of potassa until brilliant particles are no longer visible, and then washing away the sulphate with boiling water. The oxide may be procured by treating the nitromuriatic solution of gold with an excess of magnesia, and washing the precipitate, first with water, and afterwards with dilute nitric acid. This pro-
cess being tedious, M. L. Figuier prefers to obtain the oxide by precipitating the cold solution of chloride of gold, rendered strongly alkaline by caustic potassa, with a solution of chloride of barium. The precipitate, consisting of aurate of baryta, is then treated with dilute nitric acid, which dissolves the baryta and leaves the oxide of gold pure. Ten parts of gold, thus treated, produced 11.75 parts of oxide; while the same quantity of gold by the magnesia process only yielded 9 parts. (Journ. de Pharm., Dec. 1847.) The chloride is obtained by dissolving pure gold in three times its weight of nitromuriatic acid, with the aid of a moderate heat. The solution is evaporated by a gentle heat nearly to dryness, being at the same time stirred with a glass rod. It is in the form of a crystalline mass of a deep-red colour. Its solution has a fine yellow tint. Being deliquescent, it requires to be kept in ground-stoppered bottles. The iodide may be made by precipitating a solution of terchloride of gold by one of iodide of potassium, and washing the precipitate with alcohol to remove the excess of iodine. It is of a greenish-yellow colour, and, when heated in a porcelain crucible, is resolved into iodine vapours and a residue of pure gold. Chlorid of gold and sodium is prepared by dissolving four parts of gold in nitromuriatic acid, evaporating the solution to dryness, and dissolving the dry mass in eight times its weight of distilled water. To this solution one part of pure decretipated common salt is added, previously dissolved in four parts of water. The mixed solution is then evaporated to dryness, being in the mean time constantly stirred with a glass rod. The salt is of a golden-yellow colour, and, when crystallized, is in the form of long prismatic crystals, unalterable in the air. The chloroaurate of ammonia is formed by dissolving one part of the terchloride of gold and two parts of muriate of ammonia in distilled water, assisted by a few drops of nitromuriatic acid, and evaporating the solution to dryness by a gentle heat. The cyanide is best obtained, according to M. Oscar Figuier, as follows. Prepare the chloride of gold as neutral as possible by repeated solutions and crystallizations; and to the solution of this salt add, very cautiously, avoiding any excess, a solution of pure cyanide of potassium, so long as any precipitate falls. (See Potassii Cyanidum.) The precipitate, consisting of cyanide of gold, is to be washed with pure water, and dried in the dark. Gold in powder, and the oxide, chloride, iodide, sodio-chloride, and cyanide are officinal in the French Codex.

The preparations of gold are decidedly poisonous, though in different degrees. The chloride is most virulent, and, according to Dr. Christen, is even more active than corrosive sublimate. In an overdose, it produces pain, inflammation, and even ulceration of the stomach and bowels, and otherwise acts as a corrosive poison. The general effect of these preparations, in moderate doses, is to produce increased fullness and frequency of the pulse, and to augment the urine and insensible perspiration, without interfering with the appetite or the regular action of the bowels; but, if the dose be pushed too far, general irritation is apt to be produced, inflammation seizes upon some organ, according to the predisposition of the individual, and fever is developed.

Gold in powder, the oxide, chloride, and iodide are not as much used as the double chloride of gold and sodium. The oxide may be given in the form of pill, in the dose of the tenth of a grain, in scofula and lymphatic swellings, beginning with one pill daily, and afterwards gradually increasing to seven or eight in 24 hours. The chloride has been used with advantage as a caustic in lupus, and in syphilitic tubercles and ulcers by M. Chavannes. The iodide may be given in the same cases with the other preparations. The dose is from the fifteenth to the tenth of a grain.

Chloride of gold and sodium is the preparation of gold most commonly employed. It may be given in lozenges, each containing the twelfth of a grain, by mixing immediately five grains of the salt with an ounce of powdered sugar, and making the whole with mucilage of tragacanth into a proper mass, to be divided into sixty lozenges. Pills, containing the same dose, may be formed by dissolving ten grains of the dried salt in a drachm of distilled water, and forming the solution into a pilular mass with a mixture of four drachms of potato starch and one drachm of gum arabic, to be divided into one hundred and twenty pills. (Journ. de Pharm., xx. 648.) For frictions on the gums and tongue, Christen recommends the following formula: Crystallized chloride of gold and sodium one grain; powdered orris root, deprived of its soluble parts by alcohol and water, and dried, two grains. Mix. At first the fifteenth part of this powder is used daily by frictions; afterwards the fourteenth, the thirteenth, &c., until, increasing gradually, the tenth or eighth part is employed. The use of four grains of the salt in this way is said commonly to cure bad cases of recent syphilis; such, for example, as are characterized by the coexistence of chancres, warts, and buboes. In preparing this powder, lycopodium may be substituted for the orris. MM. Rouault and Debrequet have used this preparation of gold with success, in daily frictions for some minutes to the tongue, gums, and inside of the cheeks, for the resolution of chronic glandular tumours, especially those which occur in the neck in the form of a chain. The patient should swallow his saliva, while the frictions are practised. (B. and F. Medico-Chir. Rev., Am. ed., July, 1857, p. 172.)

Chloroaurate of ammonia has been recommended by Bouchardt in amenorrhoea, and dysmenorrhoea in debilitated subjects, in the dose of about the tenth of a grain. A grain may
be dissolved in five teaspoonfuls of alcohol and five of water, and a teaspoonful given morning and evening, mixed with sweetened water.

Cyanide of gold is employed, like the chloride of gold and sodium, mixed with inert powders by friction, and in the form of pill. The fifteenth of a grain may be rubbed into the gums daily for fifteen days, next the fourteenth of a grain for fourteen days, and so on, increasing until the dose amounts to the ninth or eighth of a grain. The dose for internal exhibition is the eighteenth of a grain, gradually increased to the eighth. Cyanide of gold has been found useful in the treatment of syphilis and serofula by M. Pourchon, and is said to be less exciting than the double chloride, when used in those diseases.

The different medicinal compounds of gold should not be prepared in pill, powder, or otherwise, until they are wanted for use; as they are liable to undergo decomposition when kept. They should be carefully sealed from the light.

**GRATIOLA OFFICINALIS.** Hedge-hyssop. This is a perennial herb, indigenous in the south of Europe, where it flourishes in meadows and other moist grounds. The whole herb is used. It is nearly inodorous, but has a bitter nauseous taste. Both water and alcohol extract its active properties. Its chemical constitution has been investigated by Dr. F. G. Walz, who found the following constituents: 1. gratiolin, 2. gratiolisin, 3. gratiolacin, 4. fixed oil, 5. a brown resin, 6. tannic acid, and 7. a volatile acid, the antirrhinic acid, which exists in many of the Scrophulariaceae. Each of the peculiar substances mentioned consists of carbon, hydrogen, and oxygen; the formula of gratiolin being $C_{14}H_{24}O_{6}$, that of gratiolisin $C_{14}H_{24}O_{7}$, and that of gratiolacin $C_{14}H_{24}O_{8}$. For the mode of preparing them the reader is referred to the *Am. Journ. of Pharm.* (July, 1859, p. 840), and, for a fuller account of them, to the *Chemisches Centralblatt*, Oct. 6, 1859, p. 689.

Hedge-hyssop is a domestic casting, and has a nauseous, bitterish, pungent taste. It is employed on the continent of Europe in dropsy, jaundice, dropsical and scrofulous swellings, chronic hepatic affections, serofula, and various other complaints. With us it is almost unknown as a remedy. The dose of the powdered herb is from fifteen to thirty grains; of the infusion, made in the proportion of half an ounce to the pint of boiling water, half a fluidounce.

**GROUND NUTS.** *Peanuts.* The fruit of *Arachis hypogaea*, a leguminous, annual plant, indigenous probably in Africa and South America, and abundantly cultivated in our Southern States, and elsewhere. A remarkable property of the plant is that its fruit ripens under the surface of the ground, into which the pods penetrate in the progress of their growth. The seeds constitute the well known ground-nuts of our markets, which consist of a dry, brittle envelope, and a yellowish-white kernel. These when roasted constitute for many a very agreeable article of food, and in the South are said to be much used as a substitute for coffee. They are, however, chiefly valuable on account of their richness in a fixed oil, which amounts to more than 20 per cent., and which is largely prepared in this country as an article of commerce. It is obtained by expression; the nuts being ground into a paste, and moderately heated before being submitted to pressure. As described by Mr. Jonas Winter, the oil has a bright-yellow colour, the characteristic odour of the fruit, and a mild not unpleasant taste. It is soluble in all proportions in ether, chloroform, and benzine, but insoluble in alcohol. Its sp. gr. is 0.918 at 60° F. At 38° it thickens, at 22° congeals imperfectly, and at 60° is decomposed, giving out spontaneously inflammable vapours. Mr. Winter made experiments to ascertain how far it might be employed with advantage in pharmacy, and found that it answered well in the preparation of the cerates and ointments generally; but would not serve as a substitute for olive oil in the preparation of the lead-plaster. It is a non-drying oil, and will not therefore answer for painting; but it is used for various purposes in the arts, as for lubricating machinery, and in the manufactures of wooden clothes; and would serve for burning in lamps, giving even a better light than sperm oil. (*Am. Journ. of Pharm.*, July, 1860, p. 292.)

**GUACO.** This name is given in Central and South America, and the West Indies, to various plants having supposed alexipharmic properties, and belonging to the genera *Mikania* and *Aristochloa*; but it is to the different species of the former genus that the apppellative properly belongs, and especially to *Mikania Guaco*, described by Humboldt and Bonpland. (*Pl. Ægy. ii. 84.*) The genus *Mikania* belongs to the Linnaean class and order *Syngenesia Equalis*, and to the natural order *Asteraceae*. The plants are closely allied to the Eupatoriae. For their generic character, see Lindley’s *Flora Medica*, and *Griffith’s Medical Botany*. *Mikania Guaco* is described as having twining stems, with round, sulcate, and hairy branches; ovate, subacuminate, remotely dentate leaves, somewhat narrowed at the base, rough above, and hairy beneath; and flowers in opposite axillary corymb. The plant is a native of intertropical America, and has been introduced into the W. India Islands from the continent. The leaves are the part used. In the recent state they have a bitter taste, and a strong disagreeable odour; but their sensible properties and medical virtues are impaired by drying.

This and other plants have long been employed by the natives as a preventive and cure of the bites of poisonous serpents. This application of them was first made known by
Mutis: and his account was confirmed by Humboldt and Bonpland. The medicine has also been employed as a febrifuge and anthelmintic, and a few years since attracted considerable attention for its supposed prophylactic and remedial powers in epidemic cholera and chronic diarrhoæa. It has, moreover, been recommended in chronic rheumatism, both internally and locally, and as a direct application in bites of insects, bruises and sprains, and tonic deafness. The probability, however, is that, like eupatorium, it has simply the virtues of a mild tonic, and gentle stimulant to the secretions. It is best employed in the recent state. The natives, when employing it as a counterpoison, apply the bruised leaves and expressed juice to the bite, and at the same time drink of the infusion. It is highly recommended by Dr. L. W. Pritchard in the gouty paroxysm, in which he has seldom known it to fail giving more or less relief. He gives from half a drachm to a drachm of the tincture every four hours, and applies it locally at the same time. (Pharm. Journ., Nov. 1861, p. 288.) The preparations recommended for internal use are chiefly an infusion and tincture, the former made in the proportion of an ounce of the leaves to a pint of boiling water, the latter of about a pound to the gallon of proof spirit. The dose may be about the same as that of analogous preparations of eupatorium. (See Lond. Med. Times and Gaz., Dec. 1852, p. 651, and Journ. de Pharm., 3e série, xx. 537.)

GUANO. Bird-manure. This is a valuable manure, consisting of the decomposed excrement of countless aquatic birds, which has accumulated for ages on certain barren and uninhabited islets of the western coast of South America, and in other localities throughout the world. The best comes from Peru, and will be here described. It is a coarse dry powder of a brown colour. Exposed to the air it absorbs moisture, and becomes somewhat sticky. Its smell is offensive, and slightly ammoniacal. With the powder are intermingled friable lumps, which exhibit in their inside whitish specks, and which, when exposed to the air, fall to powder, exhaling an ammoniacal smell. It is soluble in great part in water, and the solution formed contains chiefly oxalate of ammonia. When exposed to heat it blackens, burns with a slight flame, exhaled the smell of ammonia, and leaves a whitish ash, varying in amount from 27 to 35 per cent. The guanos of commerce vary very much in composition, from the best Peruvian to the inferior sorts, which have scarcely any value as fertilizers. A good specimen of guano, analyzed by Fownes, consisted of about two-thirds oxalate of ammonia, and one-third earthy and alkaline phosphates, &c. The source of oxalate of ammonia is undoubtedly the uric acid, originally in the excrement, and which is often found undecomposed in the guano. The value of guano as a fertilizer depends chiefly upon the proportion of the organic ingredients; the phosphates being of secondary importance. M. E. Baudrimont infers, from the analysis of seventeen samples of Peruvian guano, that the proportion of nitrogen may be obtained approximatively by dividing the amount of the organic matters by five. The samples varied greatly in value. (Journ. de Pharm., Oct. 1857.) Crystals of carbonate of ammonia have been observed in guano. Columbian guano was found by Dr. C. Morfit of Baltimore, to be rich in phosphoric acid and lime. (Chem. Gaz., Dec. 1, 1855.) Unger obtained from Peruvian guano, in 1846, a peculiar substance, analogous to uric (zanthic) oxide, called guanim. It forms crystallizable salts with acids, and has the formula $\text{C}_9\text{H}_8\text{N}_4\text{O}_7$. The accuracy of this formula has been confirmed by MM. Neubauer and Kerner.

In South America, guano has been used with benefit, internally and externally, as a remedy in the different forms of lepra. The late Prof. Horner, of Philadelphia, employed it as a cataplasm, mixed with an equal quantity of potters' clay, in a case of chronic inflammation of the knee-joint. In this proportion it blistered the surface; and cataplasms were afterwards adopted, containing one-third and one-fourth of guano. (Med. Exam., Feb. 1852, p. 69.) Prof. Horner attributed the revulsive effect of the guano to urate of ammonia; but the best authorities state that oxalate of ammonia is the characteristic salt of this substance. Since 1852, guano has been a good deal used in cutaneous diseases, especially in erythema, eczema, and tinea capitis. It is employed in the form of bath, lotion, and ointment. Récamier prescribed baths in these diseases, each bath containing sixteen ounces of guano; and the practice has been imitated with success by M. Desmartis, and by M. Van der Abeele, of Belgium. The lotion may be made by extracting an ounce of guano with a pint of boiling water, and filtering the solution. The ointment is formed of various strengths, from one to five parts of guano to fifteen of lard. M. C. Girardin prepares an extract of guano by extracting it with alcohol evaporated with twice its bulk of water, and evaporating the solution to a syrup. The extract has been employed as an anodyne by order of M. C. Girardin, and also a syrup, flavoured with vanilla, of which the dose is a fluid drachm, containing a grain of the extract, to be given in scrofula. The variable composition of guano must always form a serious objection to its therapeutic use.

GUN COTTON. Pyrozolin. This substance, discovered by Schünbein, of Bâle, in Switzerland, is conveniently prepared by the following process, given by Mr. Thomas Taylor, of London. Mix, in a glass vessel, $\frac{3}{4}$ fluidounces of nitric acid (sp. gr. 1-45) with an equal bulk of sulphuric acid, and, when the mixture has cooled, pour it upon 100 grains of fine cotton contained in a Wedgwood mortar, and, with a glass rod, imbue the cotton as quickly
as possible with the acids. As soon as the cotton is completely saturated, pour off the superabundant liquid, and, with the aid of the pestle, quickly press out as much of it from the cotton as possible. Then throw the cotton into a basin of water, wash it until it has not the slightest acid taste, and dry it with a gentle heat. Gun cotton may be made with strong nitric acid alone; but, as this acid is not always of full strength, it is better to mix with it sulphuric acid, which acts by strengthening the nitric acid, from its affinity for water. It may also be formed by immersing the cotton in a mixture of nitre and sulphuric acid, and this is the mode adopted in the U.S. Pharmacopoeia. (See Collodium, page 1046.)

Properties, &c. Gun cotton has the appearance of ordinary cotton, but is harsh to the touch. It is perfectly insoluble in water, and nearly so in strong alcohol; but dissolves in large quantity in acetic ether. As ordinarily made for the purpose of explosion, it is insoluble in ether; but, when carefully and freely prepared, with proper precautions, it dissolves in that menstruum, forming a powerfully adhesive liquid. (See Collodium.) According to Dr. J. H. Gladstone, of England, it is subject to spontaneous decomposition, if kept for some time. The same fact has been observed by Mr. James Beaton, of New York, and Prof. Procter, of Philadelphia. The specimen, observed by Prof. Procter to undergo decomposition, had not been well washed. The change is shown by the bottle, in which the gun cotton is kept, becoming full of nitrous acid vapour; and the substance is so far altered that it is no longer explosive, or soluble in ether. M. Bonet states that the decomposition from exposure to light takes place sooner in that which has been prepared with nitre and sulphuric acid, than where the mixed acids have been used. He says that, with both, the sides and bottom of the bottle are nearly covered with crystals of oxalic acid. (See Am. Journ. of Pharm., March, 1862, p. 183.) According to M. Béchamp, of Strasbourg, the product is soluble in ether, if the cotton be immersed in a mixture of nitre and sulphuric acid, while still hot from their reaction; but not soluble, if the cotton be added to the mixture when cold. By treating gun cotton with protoclorides of iron, M. Béchamp caused the disengagement of nitrous oxide gas, and gave the filaments a coating of oxide of iron, which was readily dissolved by muriatic acid. After this treatment the gun cotton was restored to its original state of cotton. (Chem. Gaz., Jan. 1, 1854, p. 11.) When kindled, gun cotton flashes off like gunpowder, burning without residue. Its inflaming point is at 370° F. Dr. Marx makes it lower. It has been tried as a substitute for gunpowder in fire-arms; but, from its strong bursting power, it has not been found to answer for this purpose. It appears, however, to be well adapted to rock blasting. Its composition has not been satisfactorily determined. Mr. Walter Crum, of Glasgow, makes its composition correspond with that of cellulose (cotton) \( C_{n}H_{2n}O_{n} \), in which three eqs. of water are replaced with three of nitric acid. On this supposition its formula is \( C_{n}H_{2}O_{n} + 3NO_{2} \). Porret and Teschemacher are of opinion that the cotton loses two eqs. of water, and gains four of nitric acid; so as to make its formula \( C_{n}H_{2}O_{n} + 4NO_{2} \). Another view is that three eqs. of the hydrogen are replaced by three eqs. of hyponitric acid, the oxygen which forms water with the hydrogen being derived from the nitric acid; so that the formula will be \( C_{n}H_{3}NO_{3}O_{n} + 3HO \). For some interesting observations by MM. Pelouse and Maurey on the subject of gun cotton, and particularly in reference to the modifications in the mode of preparing it, introduced by General Lenk, of Austria, the reader is referred to an article contained in the American Journal of Pharmacy (Jan. 1865, p. 36). One of these modifications consists in giving to each fibre a coating of soluble glass, by dipping the gun cotton into a solution of silicate of soda. On exposure to the air, sufficient soda combines with carbonic acid to bring the silicate to the insoluble state, so that each fibre is enclosed in an impermeable covering, which is supposed to protect it from change. But MM. Pelouse and Maurey consider this coating less beneficial than supposed by General Lenk.

**Gynocardia Odorata.** *Chaulteogra.* This is an East India plant, the fruit of which has been employed, with asserted benefit, in elephantiasis or the leprosy of the East. The fruit is a succulent indehiscent pericarp, which yields a fixed oil by expression. The seeds are used internally, and the oil applied to the ulcers. Dr. Mount has used it advantageously in leprosy, ichthyosis, scrofulous enlargements, and constitutional syphilis. He gave the seeds in the dose of six grains three times a day. (Am. Journ. of Med. Sci., N.S., xxx, 493, from Association Med. Journ., Aug. 17, 1855.)

**Humamelis Virginica.** *Witch-hazel.* An indigenous shrub, from five to fifteen feet high, growing in almost all sections of the United States, usually on hills or in stony places, and frequently on the banks of streams. It is remarkable for the late appearance of its yellow flowers, which expand in September or October, and continue till the weather becomes very cold in winter. The fruit, which is a nut-like capsule not unlike the hazel-nut, ripens in the following autumn, and is often mingled on the same plant with the new blossoms. The bark has a bitter, astringent, somewhat sweetish, and pungent taste. It probably first attracted notice as a remedy of the Indians, who are said to have used it as a sedative and diuretic in painful tumours, and other cases of external inflammation. It is used in the shape of poultice, or as a wash in the form of decoction, in hemorrhoidal affections and ophthalmia. The leaves are said to possess similar properties, and, in the state of infusion, to
be given internally in bowel complaints and hemorrhages. Dr. James Fountain, of Peckskill, N. Y., speaks in strong terms of the efficacy of the bark in hemorrhage of the lungs and stomach, and also highly recommends, as one of the best applications in external cases, an ointment prepared from lard and a decoction of equal parts of this bark, white-oak bark, and that of the apple-tree. He believes the witch-hazel to possess anodyne properties. (N. Y. Journ. of Med., x. 208.) Dr. N. S. Davis agrees with Dr. Fountain in his estimate of this remedy, which he has employed usefully in incipient phthisis. He gives it in decoction, made with an ounce of the bark to a pint of water, of which the dose is a wineglassful every three, six, or eight hours. (Transact. of Am. Med. Assoc., i. 350.) The seeds are black and shining externally, white, oily, and farinaceous within, and edible like the hazel-nut.

HARTSHORN. Cornu. Lond., Ed. This ancient medicine, having been dismissed in the recent revision of the British Pharmacopœia, and not having had a place in our own, requires to be treated of here. It was the horn of Cerbus Blaphus, the stag or hart, that was directed by the British Colleges. This species of deer inhabits Europe, Asia, and the north of Africa. The horns of our own common deer—Cerbus Virginianus—though employed in the arts, were not official. Hartshorn has been usually imported into this country from Germany, in the form of shavings. These are without smell and taste, pliable, and of an ivory yellow colour. According to M. Merat-Guillot, they contain in 100 parts, 27 of gelatin, 67.5 of phosphate of lime, 1 of carbonate of lime, and 14.5 of water including the loss. Boiling water extracts their gelatin, forming a transparent, colourless jelly, which may be rendered palatable by the addition of sugar, lemon or orange-juice, and a little wine. To prepare it, two pints of water are boiled with four ounces of the shavings to a pint, and the residue strained while hot. The liquid gelatinizes upon cooling. By destructive distillation, the shavings yield an impure solution of carbonate of ammonia, which was formerly called spirit of hartshorn; and the same name has been applied to similar ammonical solutions from other sources.

Cornu Ustum. (Lond.) Burnt Hartshorn. The directions formerly given by the London College for the preparation of this substance were, to "burn pieces of Hartshorn in an open vessel until they are thoroughly white; then powder them, and prepare them in the manner directed for Chalk." The horn must not only be heated, but also burnt, in order that the animal matter may be entirely consumed. The operation may be performed in a common furnace or stove, and the air being freely admitted. Care should be taken that the heat be not too great; as otherwise the external surface of the horn may become vitrified, and prevent the complete combustion of the interior portion, while it is itself rendered less fit for use. Burnt hartshorn consists of bone-phosphate of lime, with about 1 per cent. of free lime, derived from the carbonate contained in the horns. Calcined bone is usually sold in the shops for burnt hartshorn. For the chemical characters of bone-phosphate of lime, see Calcis Phosphas Precipitata.

Medical Properties and Uses. The opinion formerly entertained, that burnt hartshorn was antacid, has been abandoned since the discovery of its chemical nature. Its composition suggested its application to the cure of rachitis and moliities ossium, of which the prominent character is a deficiency of phosphate of lime in the bones; and it is said to have been employed in some cases, in connection with phosphate of soda, with apparent success. It is probably, however, inert. The dose is twenty grains or more. The jelly prepared from the shavings of hartshorn has been thought to possess medical virtues; but it is only nutritive and demulcent, and is in no respect superior to calves-foot jelly. The shavings themselves were formerly used in the preparation of Pulvis Antimonialis.

HEDERA HELIX. Ivy. This well-known evergreen creeper is a native of Europe. The fresh leaves have a balsamic odour, especially when rubbed, and a bitterish, harsh, unpleasant taste. They are used for dressing issues, and, in the form of decoction, have been recommended in sẵnious ulcers and cutaneous eruptions, particularly tetter and the itch. Dried and powdered, they have been employed in the atrophy of children, and in complaints of the lungs, in the dose of a scruple or more. The berries, which have an acidulous, resinous, somewhat pungent taste, are said to be purgative and even emetic. MM. Vandamme and Chevallier discovered in ivy seeds a peculiar alkaline principle, which they called hedergin (hedera). It is very bitter, and appears to be closely allied to quinina in febrifuge properties. It is obtained by treating the seeds with hydrate of lime, dissolving the precipitated alkaloid in boiling alcohol, and evaporating the alcoholic solution. (Am. Journ. of Pharm., xiii. 172.) Prof. Posselt has discovered two acids in the seeds, one of which has its taste in a high degree, and was named by him hedric acid, the other he did not obtain quite pure. (See Chem. Gaz., March 1, 1849, p. 36.) From the trunks of old ivy plants, growing in the south of Europe and the north of Africa, a resinous substance exudes through incisions in the bark, which has been employed in medicine under the name of ivy gum. It is in pieces of various sizes, of a dark yellowish-brown colour sometimes inclining to orange, more or less transparent, sometimes of a deep ruby-red colour internally, of a vitreous fracture, pelverizable, yielding a lively orange-yellow powder, of a peculiar not disagreeable colour when heated or inflamed, and of a bitterish resinous taste. Its chief constituent is resin, though some pieces contain a considerable proportion of bassorin, and others large quantities of
ligneous matter. It was formerly used as a stimulant and emmenagogue, but is now scarcely employed. Placed in the cavities of carious teeth, it is said to relieve toothache. The wood of the ivy, which is light and porous, is sometimes used for making issue-peas.

HELENIUM AUTUMNALE. False Sunflower. Sneezewort. An indigenous perennial herb, from three to seven feet high, with large, golden-yellow, compound flowers, which appear in August. It grows in all parts of the United States, flourishing best in meadows, moist fields, and other low grounds. All parts of it are bitter and somewhat acrid, and, when snuffed up the nostrils in the state of powder, produce violent sneezing. The leaves and flowers have been recommended as an excellent errhine. Clayton says that the plant is thought to be useful in intermittent fever.

HELLEBORUS FETIDUS. Bear's-foot. This is a perennial European plant, growing in shady places, and flowering in March and April. It derived its botanical designation from its offensive odour. The leaves, which are the part used, have a bitterish, pungent, and acrid taste, and when chewed excoriates the mouth. The foot-stalks are still more acrid. This species of hellebore is said by Allioni to be the most acrid and energetic of the plants belonging to the genus. It is powerfully emetic and cathartic, and in very large doses produces dangerous effects. It has long been used in Great Britain as a domestic remedy for worms, and was brought to the notice of the profession by Dr. Bisset, who found it an efficacious anthelmintic, and prescribed it also in asthma, hysteria, and hypochondriasis. M. Decers has known it to cause the expulsion of taenia. It is given in powder or decoction. The dose for a child from two to six years old is from five grains to a scruple of the dried leaves, or a fluidounce of the decoction, made by boiling a drachm of the dried leaves in half a pint of water. This quantity should be repeated, morning and night, for two or three days in succession. A syrup made from the juice of the green leaves is used in England.

HELONIAS DIOICA. False Unicorn Plant. Star-wort. This is a small perennial herbaceous plant, growing in most parts of the United States, in shady and hilly situations. The root, which is the part used, is bulbous. Pursh says that it is used as a remedy in colic. Dr. Braman has found it peculiarly efficacious in atony of the generative organs, and has obtained great advantages from it in leucorrhea. He states the dose of the powdered root at a drachm and a half, three times a day. It may also be given in the forms of syrup and tincture. (Bot. Med. and Surg. Journ., xl. 410.)

HERACLEUM LANATUM. (Michaux, Flor. Boreat. Am. i. 166.) Masterwort. This is one of our largest indigenous umbelliferous plants. It belongs to Pentandria Diginia in the Linnaean system, with the following generic character. "Fluit elliptical, emarginate, compressed, striated, margined. Corolla difforn, inflexed, emarginate. Involucrc caducous." (Wild.) The root is perennial, sending up annually a hollow pubescent stem, from three to five feet high, and often more than an inch thick. The leaves are ternate, downy beneath, and supported on downy footstalks; the leaflets petiolate, roundish-cordate, and lobed. The flowers are white, in large umbels, and followed by orbicular seeds. Like the European species this is sometimes called cow-parsnip. It grows in meadows and along fences and hedges, from Canada to Pennsylvania, and flowers in June. The root, which is the official part, bears some resemblance to that of common parsley. It has a strong disagreeable odour, and a very acrid taste. Both the leaves and root excite redness and inflammation when applied to the skin. Dr. Bigelow considers the plant poisonous, and advises caution in its use, especially when it is gathered from a damp situation. Masterwort appears to be somewhat stimulant and carminative, and was used successfully by Dr. Orne, of Salem, Massachusetts, in cases of epilepsy, attended with flatulence and gastric disorder. He directed two or three drachms of the pulverized root to be taken daily, for a long time, and a strong infusion of the leaves to be drunk at bedtime.

HERMODACTYLY. Hermodactyl. Under this name are sold in the shops of Europe the roots or bulbs of an uncertain plant, growing in the countries about the eastern extremity of the Mediterranean. By some botanists the plant is considered a species of Colchicum; and C. variegatum, a native of the south of Europe and the Levant, is particularly indicated by Fée, Geiger, and others; while by authors less eminent, the roots are confidently referred to Iris tuberosa. They certainly bear a considerable resemblance to the bulb of Colchicum autumnale, being heart-shaped, channeled on one side, convex on the other, and from half an inch to an inch in length, by nearly as much in breadth. As found in the shops, they are destitute of the outer coat, of a dirty yellowish or brownish colour externally, white and amylaceous within, inodorous and nearly tasteless, though sometimes slightly acid. They are often worm-eaten. Their chief constituent is starch, and they contain no veratria or colchicia. From this latter circumstance, and from their insipidity, it has been inferred that they are probably not derived from a species of Colchicum; but Geiger observes that they may have lost their acrimony by age. They are in fact almost without action upon the system, and are now seldom used; never, we believe, in this country. It is doubted whether they are the hermodactyl of the ancients, which were certainly
Hibiscus Abelmoschus.—Hydrangea Arborescens. PART III.

A powerful medicine, operating very much in the same manner as our colchicum, and like it proving useful in gout and rheumatism. Pereira describes a bitter variety of hermodactylus, which was brought from India by Dr. Royle. The bulbs are smaller and darker than the others, and have externally a striped or reticulated appearance. From their bitter taste they are probably more active.

HIBISCUS ABELMOSCHUS. Abelmoschus moschatus. Wight and Arnott. An evergreen shrub, growing in Egypt, and in the East and West Indies, and yielding the seeds known under the names of semen Abelmoschi, alece Eupylesin, and grana moschatia. These are of about the same size as flaxseed, kidney-shaped, striated, of a grayish-brown colour, of an odour like that of musk, and of a warm somewhat spicy taste. They were formerly considered stimulant and antispasmodic; but are now used only in perfumery. The Arabs flavour their coffee with them. They are said to be employed in the adulteration of musk.

Another species, *Hibiscus esculentus*, or *Abelmoschus esculentus* of Wight and Arnott, is cultivated under the name of okra, bendee, or gombo, in various parts of the world, for the sake of its fruit, which abounds in mucilage, and is used for thickening soup. The leaves are sometimes employed for preparing emollient poultices. The roots, which are a foot or two long, are said also to abound in mucilage, of which they yield twice as much as the althea root from the same weight, free from any unpleasant odour. Their powder is perfectly white, and superior also to that of the marshmallow. The plant is largely cultivated near Constantinople, where it is much used as a demulcent. (Am. Journ. of Pharm., May, 1860, p. 224.)

HIERACIUM VENOSUM. Rattlesnake Weed. (Gray's Manual, p. 287.) The plants belonging to the genus *Hieracium* are generally called hawkweed; but the *H. venosum* has been distinguished by a special name, derived from its supposed efficiency as an antidote to the bite of the rattlesnake. They are all perennial herbs belonging to the natural family of the Compositae. The rattlesnake weed has a smooth slender flower-stem, one or two feet high, either naked or furnished with but a single leaf, and dividing at top into a loose spreading corymb of yellow flowers. The plant is common, growing in dry places and open woods, in most of the eastern and northern parts of the United States. The leaves and root are thought to possess medical virtues, and, being deemed astringent, have been used in hemorrhagic diseases. The juice is supposed by some to have the power of removing warts. The medicine may be given in infusion, made in the proportion of two ounces to the pint, of which the dose is a wineglassful.

HURA BRASILIENSIS. Assacou. Hura Brasiliensis of Martius is a Brazilian tree belonging to the family of Euphorbiaceae, and known to the natives of the country it inhabits by the name of assacou. Another species of the same genus, *H. crepitans*, growing in the West Indies, and characterized by the tendency of its fruit to break when ripe with violence into several pieces, and thus scatter the seeds, has long been known as an acrid emetic-cathartic, capable in large doses of acting as a violent poison. The fresh juice, the seeds, and a decoction of the bark, all have these properties, which, in fact, belong in a greater or less degree to most of the Euphorbiaceae; and, as in other members of the same family, an oil expressed from the seeds is actively purgative. It is highly probable that the Hura Brasiliensis is similar in all these respects to its congner. Martius states that the juice is anthelmintic, and employed to intoxicate fish. But attention has recently been especially attracted to the plant, in consequence of reports favourable to its efficacy in that terrible scourge of Brazil, the elephantiasis or leprosy of the country. These reports were received by the Academy of Medicine, of Paris, from the French Consul in one of the towns of Para, of which province the natives are said to regard the remedy as a specific in the complaint referred to. Experiments have been made by the Brazilian physicians, and it is said with favourable results, though complete cures have not been obtained. The fact is that various acrid emeto-cathartic medicines, capable also of producing diaphoresis, have been more or less useful in elephantiasis, as the Calotropis gigantea, and one or more species of Iodidium; and it is probable that the assacou acts in a similar manner, and with similar results. The milky juice of the plant, and an infusion or decoction of the bark are used. The juice is extremely acrid, producing on the skin, when applied to it, an erysipelas redness and a pustular eruption; and the natives are said to employ it in the preparation of a poison. A grain of the juice made into a pill, or a scrupule of the bark infused in a pint of water, is given every day, and gradually increased as the stomach and bowels will bear it. Every week an emetic preparation is administered, made by boiling half an ounce of the bark in a pint of water to half a pint, to which twelve drops of the juice are added. Every second or third day the patient takes a bath, consisting of a saturated infusion of the bark. (Journ. de Pharm., xiv. 424.)

HYDRANGEA ARBORESCENS. Common Hydrangea. Seven Barks. This species of Hydrangea is indigenous, growing in shady places, in the woods and on the banks of streams throughout the Middle and Southern States. It is a shrub from four to eight feet high, with ovate or cordate leaves, from three to six inches long, generally acuminate, serrately
toothed, and slightly pubescent, or nearly glabrous. The flowers are in fastigate cyms, and appear in July. For a particular botanical description of the plant, the reader is referred to Torrey and Gray’s Flora of North America (i. 591). The root, which is the part used, consists of a caudex, from which proceed numerous radicles, from the thickness of a quill to that of the finger or more. For use it should be cut into transverse pieces when fresh, and then dried. The taste is aromatic, pungent, and not unpleasant. The root was analyzed by Mr. Laidley, of Richmond, Va., who found in it gum, albumen, starch, resin, and various salts, among which was a proteosalt of iron. (Am. Journ. of Pharm., xxiv. 20.)

Attention was first called to it as a remedy in the New Jersey Med. Reporter for Oct. 1856 (p. 44), by Dr. S. W. Butler, whose father, Dr. E. Butler, long residing as a missionary among the Cherokee Indians, employed it with great apparent advantage in their calculous complaints. Reports of cases, tending to confirm the opinion of its utility in “sabulous or gravelly deposits” in the urine, have since been published by Drs. W. L. Atlee, D. Horsley, and John C. S. Monkur. (Ibid., Sept. 1854, pp. 393 and 416, Oct. 1854, p. 426, and March, 1856, p. 115.) Dr. Butler used it in the form of decoction, or of a syrup made from the decoction with sugar or honey. A strong syrup may be given in the dose of a teaspoonful three times a day. In overdoses it occasions vertigo, oppression of the chest, &c. W.

HYDRODIC ETHER. Ether Hydriodicus. Iodide of Ethyl. This ether may be obtained by gradually and cautiously mixing five parts of alcohol, ten of iodine, and one of phosphorus, and distilling. The residue of the distillation, as ascertained by D. K. Tuttle, is phosphoric acid. The best mode of proceeding, in order to avoid danger, according to Soubeiran, is to melt the phosphorus with a gentle heat under the alcohol, contained in a wide-mouthed matras, and to add the iodine gradually through a tube, sealed at the lower end, but perforated at the same end with a number of small holes. The tube is made to pass through a grooved cork, to give exit to the vapours, and is so adjusted as to reach nearly to the surface of the melted phosphorus. The matter in the matras is distilled to the extent of four-fifths, the distillate is washed with water to separate alcohol, and the decanted ether is dried by the addition of a few pieces of chloride of calcium. Dr. de Vrij recommends the following method for procuring this ether on a large scale. Absolute alcohol is to be saturated with dry muriatic acid gas, the liquid being kept well cooled; and the amount of the acid is to be determined by a sample. The liquid thus saturated is to be put into a retort with as much iodide of potassium as may be necessary to form chloride of potassium; the mixture is to stand for a day; and is then to be submitted to distillation. Finally, the ether which comes over is to be washed and rectified. (See Am. Journ. of Pharm., March, 1859, p. 170.) Hydriodic ether is a colourless non-inflammable liquid, insoluble in water, with a penetrating ethereal odour and pungent taste. Its density is 1·92, and boiling point 158°. When exposed to the air it becomes red from the liberation of iodine, a change which is prevented by adding to the bottle containing it, a globule of mercury. Being an iodide of ethyl, its formula is C{H,Cl, I. M. Huette has proposed this ether as a medicine, to be used by inhalation, placed under a layer of water. Fifteen or twenty inspirations suffice to impregnate the system with iodine. Its physiological effects appear to be those of an antispasmodic and general stimulant. It acts also as a powerful amnesthetic, when sufficiently long inhaled. It increases the appetite, renders the pulse fuller, and gives vivacity to the feelings and activity to the intellect. M. Huette considers it a suitable preparation for bringing the system rapidly under the influence of iodine, and by any desired dose. (See Am. Journ. of Pharm., xxxii. 156.) Since the therapeutic trials of M. Huette were made, Mr. James Turnbull, of Liverpool, and Dr. Henry Fisher, of New York, have used this ether by inhalation in chronic pulmonary diseases with satisfactory results. Dr. Fisher specifies chronic bronchitis and phthisis as the diseases in which he has found it useful. The dose is 15 drops, three or four times a day, inhaled from a handkerchief. Hydriodic ether often has an unpleasant smell from the presence of foreign substances, which render it offensive to patients. Phosphorus is a common and injurious impurity. B.

HYDROCOTYLE ASIATICA. Thick-leaved Pennywort. Brevilagia. Boilean. This is a small umbelliferous plant, with a trailing stem, and, from the shape of its leaves, bearing some resemblance to the violet. It grows in moist grounds in India, Southern Africa, and the islands of the Indian Ocean. It has long been ranked among the medicinal plants of India, where it has been used as an alterative to purify the blood. An elaborate analysis has been made of it by M. Jules Lépine, who discovered in it a particularly pungent substance which he calls vellarine, and in which he supposes the active properties to reside. It has a strong odour recalling that of the plant, and a bitter, pungent, and persistent taste. (Journ. de Pharm., Juillet, 1856, p. 49.)

The plant has been supposed to possess diuretic properties; and, according to Ainslie, is employed in infusion with fenugreek in fever and bowel complaints. But it has recently attracted attention, from the claims strongly urged in its favour as a remedy in that most obstinate affection often called leprosy, but more correctly leprophatiasis of the Greeks. It was first employed in this complaint by Dr. Boileau, of the Island of Mauritis, who was himself a victim of the disease, and had resorted to this remedy under the false impression
that it might be identical or analogous with the cuichunchillii. He was so much pleased with its effects that he was induced to try it upon others; and a great many lepers were put under its influence. All the cases were arrested, many were benefited, and in some the disease almost disappeared. The statements of Dr. Boileau have been supported by those of M. Lépine, of Pondicherry, and the medicine would certainly seem to merit a thorough investigation. Dr. Boileau, probably at first in ignorance of its botanical title, gave it the name of bevilacqua. He used it in powder, infusion, and syrup. An ounce of the dried plant may be given daily, in the form of infusion made with a pint of water. This should be continued for several weeks, combined with baths, and attention to the state of the bowels. After this preparation, the syrup is to be given in spoonful doses three times a day, to be gradually increased after three weeks, if no improvement has taken place, to eight spoonfuls daily. The powder may be added to the syrup, if deemed necessary, in the dose at first of fifteen grains, to be increased cautiously to a drachm. (Journ. de Pharm., 3e sér., xxiv. 424, and xxv. 168.) This account of the remedy has been in some measure confirmed by the testimony of Mr. E. J. Waring, of the Madras Medical Service, and Dr. Hunter, who have found it especially useful in secondary syphilis and scrofulous ulcers. (Pharm. Journ., Aug. 1860, p. 148.) M. Lecoq, however, has been led by his experience and observation to the conclusion, that no sufficient evidence exists of any case of leprosy cured by this remedy, and that it is equally inefficient in other diseases of the skin. (Ann. de Thérap., 1859, p. 79.)

HYDROCYANIC ETHER. Ether Hydrocyanicus. Hydrocyanate of Ethyl. Cyanide of Ethyl. Cyanuret of Ethyl. This ether was discovered by Pelouze. It is formed by distilling a mixture of sulphovanate of baryta and cyanide of potassium. It is a colourless liquid, of a penetrating garlic odour, soluble in alcohol and ether, sparingly soluble in water, boiling at 180°, and weighing specifically 0.78. It is very poisonous, but less so than hydrocyanic acid, with which it agrees in therapeutic action and dose.

HYDROSULPHATE OF AMMONIA, SOLUTION OF AMMONIA HYDROSULPHURICUM. Dub. Solution of Hydro sulphuret of Ammonia. Br. Appendix. This former official of the Dublin Pharmacopoeia was prepared in the following manner. "Take of Solution of Ammonia four fluidounces [Imperial measure]; Sulphuret of Iron one ounce and a half [avoirdupois]; Oil of Vitriol of Commerce one fluidounce and a half [Imp. meas.]; Water fifteen ounces [avoird.]; Distilled Water two ounces [avoird.]. Place the Sulphuret of Iron and Water in a two-necked bottle, and, adding the Oil of Vitriol by degrees through a safety funnel, conduct by suitable tubes the sulphuretted hydrogen which is disengaged, first through the Distilled Water placed in a small immediate vial, and then to the bottom of a bottle containing the Ammonia, the neck of the latter, through which the glass tube conveying the gas passes, being loosely plugged with tow. If, when the development of gas has ceased, a drop of the ammoniacal liquid, added to a saturated solution of sulphate of magnesia, gives no precipitate, the preparation is completed; but, should a precipitate occur, the hydro sulphuret still contains free ammonia, and must, therefore, be again subjected to the action of a stream of sulphuretted hydrogen. The Hydro sulphuret of Ammonia must be kept in a green glass bottle, furnished with an accurately ground stopper. The specific gravity of this solution is 0.990." (Dub.) This preparation is a solution of bithydro sulphate of ammonia in water, and is formed by passing a stream of hydro sulphuric acid gas (sulphured hydrogen), that of water of ammonia, contained in a Woulfe bottle. Considered as a bithydro sulphate, its formula is NH₂HS; but it is probably a sub hydro sulphate, with the formula NH₃HS, and is so considered in the British Pharmacopoeia, where it holds a place among the test solutions in the Appendix. The hydro sulphuric acid is obtained by acting with dilute sulphuric acid on sulphuret of iron. The water yields its oxygen to the iron forming protoxide of iron, with which the sulphuric acid combines; while the hydrogen of the water, uniting with the sulphur, generates hydro sulphuric acid.

Hydro sulphuret of ammonia is a liquid of a greenish-yellow colour, very fetid smell, and acid, disagreeable taste. It is characterized by giving coloured precipitates with neutral metallic solutions, for which it is much used as a test. It is decomposed by acids, which cause the escape of hydro sulphuric acid with effervescence, and the deposition of sulphur. This preparation is sedative, lessening the action of the heart in a remarkable degree, and producing, when given in large doses, nausea, vomiting, vertigo, and drowsiness. It was proposed as a remedy in diabetes mellitus, by Dr. Cruickshank, for the purpose of lessening the morbid appetite in that disease, and has been employed by Dr. Rolle and others. The dose is five or six drops in a tumblerful of water three or four times a day, to be gradually increased until giddiness is produced.

HYPERICUM PERFORATUM. St. John's Wort. A perennial herb, abundant both in Europe and this country, often covering whole fields, and proving extremely troublesome to farmers. It is usually from one to two feet high, with leaves which, from the presence of numerous transparent vesicles, appear as if perforated, and have hence given origin to the botanical designation of the plant. The flowers, which are numerous and of a deep-yellow colour, appear during the summer from June to August. The flowering summits are
the parts used, though the unripe capsules are possessed of the virtues of the plant in an
equal degree, and the seeds are said to be even stronger. St. John's wort has a peculiar
balsamic odour, which is rendered more sensible by rubbing or bruising the plant. Its taste
is bitter, resinous, and somewhat astringent. It imparts a yellow colour to cold water, and
reddens alcohol and the fixed oils. Its chief constituents are volatile oil, a resinous sub-
stance, tannin, and colouring matter. As a medicine it was in high repute among the an-
cients, and the earlier modern physicians. Among the complaints for which it was used
were hysteria, mania, intermittent fever, dysentery, gravel, hemorrhages, pectoral com-
plaints, worms, and jaundice; but it was, perhaps, most highly esteemed as a remedy in
wounds and bruises, for which it was employed both internally and externally. It is diff-
cult to ascertain its exact value as a remedy; but, from its sensible properties, and from
the character of the complaints in which it has been thought useful, it may be considered,
independently of its astringency, as somewhat analogous in medical power to the turpen-
tines. It formerly enjoyed great reputation for the cure of demoniacs; and the superstition
still lingers among the vulgar in some countries. At present the plant is scarcely used ex-
cept as a domestic remedy. The summits were given in the dose of two drachms or more.
A preparation was at one time official, under the name of oleum hyperici, made by treating
them with a fixed oil. It has a red colour, and is still used in many families as a sovereign
remedy for bruises. It is commonly called red oil.

W. HYPOPHOSPHITES. Attention has been called to these salts, in consequence of their
recommendation by Dr. Churchill, of Paris, in the treatment of phthisis, in which they are
thought to be useful by furnishing phosphorus to the tissues. A paper on their mode of
preparation and qualities was communicated by Prof. Procter to the American Journal of
Pharmacy (March, 1856, p. 118), to which we are indebted for much of what follows on the
chemistry of the subject. Hypophosphorus acid consists of one eq. of phosphorus and one
of oxygen, and always contains two or three eqs. of water. It has a strong affinity for
oxygen, and acts therefore as a powerful deoxidizing agent, and carries this property as
well as water with it into composition. When heated it is resolved into phosphuretted
hydrogen and phosphoric acid. Its salts are generally soluble in water and deliquescent,
and many of them are soluble in alcohol. They are converted into phosphates by heat,
with the escape of phosphuretted hydrogen; and some of them are explosive.

Hypophosphate of lime has attracted most attention, and would meet the views of those who
wish to supply phosphate of lime to the system, as the hypophosphorous acid is converted
into the phosphoric by its deoxidizing power. To prepare it Prof. Procter gives the following
formula: Slake 4 lbs. avoid. of lime with a gallon of water, add it, in a deep boiler, to 4
gallons of boiling water, and mix thoroughly. To the mixture add a pound avoid. of
phosphorus, and continue the boiling, adding hot water from time to time to keep up the
mixture, until the combination is complete, and phosphuretted hydrogen is no longer
evolved. It is necessary that provision should be made for the escape of the gas, which
takes fire spontaneously in contact with the air. There are formed in the liquid phosphate
and hypophosphate of lime, the phosphorus having become oxidized at the expense of the wa-
ter, the hydrogen of which has escaped in combination with another portion of phosphorus,
which is therefore lost. The liquid is filtered to separate the insoluble phosphate and re-
siduary lime, then concentrated, and refiltered to separate the carbonate of lime formed
by the action of the air on a little lime held in solution, and lastly evaporated till a pellicle
appears: after which the salt may be allowed to crystallize by setting the liquid aside, or
may be obtained in the granular form by continuing the heat, and stirring. The salt should
be introduced into bottles. It is white, of a somewhat pearly lustre, and crystallizes in daf-
ttened prisms. It is soluble in 6 parts of cold water, little more so in boiling water, and
slightly soluble in diluted, but insoluble in official alcohol. Its formula is CaO.\(\text{PO}_3\)\(\cdot\)H\(\text{O}\).

Hypophosphate of soda is prepared by mixing solutions of hypophosphite of lime and
crystallized carbonate of soda, in the proportion of 6 ounces of the former dissolved in 4
pints of water, to 10 of the latter in one and a half pints. Double decomposition takes
place, with the formation of carbonate of lime and hypophosphite of soda, of which the
latter is held in solution, and the former precipitated. After filtration to separate the car-
bonate of lime, the solution is evaporated to a pellicle, and then stirred constantly till the
salt granulates, the heat being continued. If required quite pure, the granulated salt is
dissolved in official alcohol; and the liquid, having been evaporated to a syrupy consist-
ence, is set aside to crystallize. Sometimes the hypophosphate of soda explodes with vio-
ence during the evaporation of its solution. This was ascribed to the use of too high a
heat; but the same accident has occurred when the heat was applied by means of a water-
bath. (See Am. Journal of Pharm., Jan. 1860, p. 87.) In a communication of Mr. Tuson to the
Chemical News (Ne. 31, p. 46), it is stated that, though he had superintended the manufac-
ture of large quantities of the hypophosphites of lime and of soda, he had never witnessed
anything like an explosion; but the heat employed in evaporation had never approached
212°; and this is probably the true explanation. Caution, therefore, should be observed
to evaporate at a low temperature. Hypophosphite of soda crystallizes in rectangular
Hypophosphite of Lime.—Hyraseum. PART III.

Tables of a pearly lustre, deliquesces on exposure, and is soluble both in water and alcohol. Its formula is Na₂O₅H₂O₃PO₃.

Hypophosphite of potassa is prepared in the same manner as the salt of soda; 5·76 ounces of granulated carbonate of potassa, dissolved in half a pint of water, being substituted for the carbonate of soda. This salt is still more deliquescent than the preceding, and therefore less eligible. Its formula is KO₂H₂O₃PO₃.

Hypophosphite of ammonium may be obtained in like manner from hypophosphite of lime and sulphate or sesquicarbonate of ammonia; and the hypophosphite of sesquioxide of iron from solution of hypophosphite of soda or ammonia with solution of sulphate of sesquioxide of iron. A hypophosphite of quinia has also been proposed. (Chem. Gaz., No. 43, p. 186.) Prof. Procter gives a formula for preparing hypophosphorous acid, which consists in decomposing hypophosphite of lime in solution by oxalic acid, which precipitates the lime, leaving the hypophosphorous acid in solution. The quantities are so proportioned that a fluidrachm shall contain 6 grains of the acid, equivalent to about 2·25 grains of phosphorus. The dose of the acid is therefore from ten minims to a fluidrachm.

As the soluble salts of mercury and silver are reduced by the hypophosphites, they are of course incompatible with it in prescriptions. With the hypophosphite of lime, all the soluble sulphates and carbonates produce precipitates. The hypophosphite of iron may be given with the preparations of cinchona, as, though blackened by the tannic acid of galls, it is not so by cinchono-tannic acid. As these salts are insoluble in cod-liver oil, they should be dissolved in syrup before being added to the oil. Prof. Procter prepares a syrup of hypophosphite of lime by dissolving a trooounce of the salt in 5-6 fluidounces of water, then adding 12 trooounces of sugar and dissolving with a gentle heat, and finally adding half a fluidounce of the fluid extract of vanilla. The dose of the syrup is from one to four fluidrachms, three times a day. A compound syrup is prepared by the same writer, containing the hypophosphites of lime, soda, potassa, and iron, with hypophosphorus acid, a formula for which will be found in the same communication to which reference has been made above.

The author does not wish to be understood as recommending these remedies in consumption. The weight of testimony appears to him to be opposed to the first favourable impressions; and, though some cases may have seemed to be benefited, yet great care must be taken not to allow a reliance on the hypophosphites to interfere with the use of remedies known to be efficient, as cod-liver oil and supporting measures generally. The dose of either of the hypophosphites may be from ten to thirty grains, three times a day. W.

HYPOSULPHITE OF LIME. Calcis Hyposulphit. Under the head of Soda Hyposulphite, page 792, reference is made to hyposulphite of lime, as possessing with other hyposulphites, useful properties in the destruction of the lower forms of animal and vegetable life, by which the human system is often seriously infested; and the hope is even indulged that it may become a most useful agent in the prevention and relief of a class of diseases depending on infection of the blood. The following mode of preparing it is recommended by M. J. Lanneau of Paris. Take 1000 parts of sulphur, 400 of lime, and 4000 of rainwater; slake the lime with sufficient of the water, add the sulphur and the residue of the water, and boil for an hour and a half, adding water to keep up the measure; when cool filter the liquid through linen covered with filtering paper; and wash the residue with 1000 parts of water. A solution is thus obtained of polysulphuret of calcium of the sp. gr. 1·141. Into this pass a current of washed sulphurous acid gas until the solution becomes colourless; separate the sulphur precipitated (which may be used for the officinal Precipitated Sulphur); and evaporate the clear solution at a heat not exceeding 140° F., until it begins to crystallize, when it is to be set aside. The product is 700 parts of hyposulphite of lime. This is in six-sided crystals, which effloresce in a dry air. M. Lanneau prepares a syrup of the hyposulphite by dissolving 10 parts of the crystallized salt in 20 parts of distilled water, and mixing with the solution 170 parts of syrup of orange flowers. (See Am. Journ. of Pharm., May, 1863, p. 228.) The dose of the salt is from ten to twenty grains three times a day, of the syrup from two to four fluidrachms. W.

HYPOSULPHITE OF SODA AND SILVER. Sodae et Argenti Hyposulphur. This double salt may be prepared by dissolving freshly precipitated oxide of silver in a solution of hyposulphite of soda, and evaporating the solution. It is in the form of minute crystals, very soluble in water, but insoluble in alcohol, and possessing a very sweet taste. Its solution, protected from the light, undergoes no change, and, when quite pure, does not discolor the skin or linen. M. Delioux, of Rochefort, has tried this salt externally only, and thinks it acts like nitrate of silver, but more mildly. He used it with advantage, especially in urethral discharges, dissolved in the proportion of one or two parts in two hundred of water. (B. and F. Medico-Chir. Rev., Am. ed., April, 1853, p. 447, from the Bull. de Thérap.) B.

HYRACEUM. Under this name, a substance from the Cape of Good Hope has been introduced to the notice of the profession, in Europe, as a substitute for castor. It is the
product of *Hyrax Capensis*, an animal of South Africa, about the size of a large rabbit. It is said to be collected in small pieces on the rugged sides of mountains, and is probably the excrement of the animal. It is rather hard, tenacious, of a blackish-brown colour, and in taste and smell not unlike castor. It is inflammable, and yields portions of its constituents to water and alcohol. Examined with the microscope, it has been found to contain vegetable tissues, animal hairs, sand, and globular particles, either resinous or oily. Schrader has found it to contain stearin, a gum-resin soluble in absolute alcohol, an odorous yellow substance soluble in ordinary alcohol and in water, a brown substance soluble in water, and insoluble residue. Dr. Pereira, from whose paper the above account is extracted, considered it worthless as a therapeutic agent, though in physiological effects it is said exactly to resemble American castor. (Pharm. Journ., x. 123.) For an elaborate paper on this substance by M. J. Léon Soubeiran, see Journ. de Pharm. (xxix. 376).

**HYSSOPUS OFFICINALIS. HYSSOP.** This is a labiate plant, belonging to the class and order Dindynamia Gymnosperma of the sexual system. It is perennial, with numerous erect, quadrangular, somewhat branching stems, which are woody in their interior portion, about two feet high, and furnished with opposite, sessile, lanceolate-linear, pointed, punctate leaves. The flowers are violet-coloured or blue, sometimes white, turned chiefly to one side, and arranged in half verticillated, terminal, leafy spikes. The upper lip of the corolla is roundish and notched at the apex, the lower is divided into three segments, of which the undermost is obovate.

Common hyssop is a native of Europe, where, as well as in this country, it is cultivated in gardens. The flowering summits and leaves are the parts used. They have an agreeable aromatic odour, and a warm, pungent, bitterish taste. These properties they owe to an essential oil, which may be separated by distillation with water, and rises also with alcohol. Hyssop is a warm, gently stimulant aromatic, applicable to the same cases as the other labiate plants. Its infusion has been much employed in chronic catarrhs, especially in old people, and those of a debilitated habit of body. It acts by facilitating the expectoration of mucus when too abundantly secreted. In this country, however, it is seldom used by regular practitioners.

**IBERIS AMARA. BITTER CANDYTUFT.** A small herbaceous plant, indigenous in Europe, where it is cultivated in gardens on account of its bright milk-white flowers. The leaves, stem, and root are said to possess medicinal properties; but the seeds are the most efficacious. The plant appears to have been employed by the ancients in rheumatism, gout, and other diseases. It was again brought into notice by Dr. Silvester, who ascribed to the late Dr. Williams, of St. Thomas's Hospital, London, the merit of having first ascertained its real therapeutic value. In large doses it produces giddiness, nausea, and diarrhoea; but its virtues do not seem to be associated with any perceptible physiological effect. It is thought to exercise a happy influence over the excited actions of the heart, and is especially useful in hypertrophy. Much advantage is also said to have accrued from it in asthma, bronchitis, and dropsy. The dose of the seeds is from one to three grains. (Proc. Med. and Surg. Journ., July 28, 1847.)

**ILEX. HOLLY.** Several species of Ilex are employed in different parts of the world. The *I. Aquifolium*, or common European holly, has attracted much attention in France. It is usually a shrub, but in some places attains the magnitude of a middling-sized tree. Different parts of it are used. The viscid substance called birdlime is prepared from the inner bark. The leaves, which are of a bitter, somewhat austere taste, were formerly much esteemed as a diaphoretic, and in the form of infusion were employed in catarrh, pleurisy, small-pox, gout, &c. A few years since they gained some reputation in France as a cure for intermittent, and were considered by some as equal to Peruvian bark; but the first reports in their favour have not been fully confirmed. They were used in powder, in the dose of a drachm two hours before the paroxysm; and this dose was sometimes repeated frequently during the apyrexia. Their febrifuge virtues are said to depend on a bitter principle, for which the name of tina has been proposed. M. Labourdais obtained this principle by boiling a filtered decoction of holly leaves with animal charcoal, allowing the charcoal to subside, washing it, then treating it with alcohol, filtering off the alcoholic solution, and evaporating it to a syrupy consistence. The liquid thus obtained was very bitter, and, on being allowed to evaporate spontaneously, yielded an amorphous substance, having the appearance of gelatin, which was the principle in question. (See Am. Journ. of Pharm., xxi. 89.) A yellow colouring substance, called *ilexanthin*, and a peculiar acid, called *ileic acid*, have been obtained by Dr. F. Moldenhauer. Ilexanthin is obtained in the following manner. The leaves are exhausted with alcohol, the alcohol is distilled off, and the residue set aside for several days. A sediment forms, which is separated from the mother-liquor, treated with ether to remove the chlorophyll, and then purified by repeated solution in alcohol and crystallization. The composition of ilexanthin is C_{44}H_{60}O_{16}. It crystallizes in yellow needles, which change colour at 365° F., melt at 388°, and at 417° boil with decomposi
tion, and are not sublimable. It is insoluble in ether, but soluble in alcohol. In cold water it is almost insoluble; but hot water dissolves it freely, and deposits it in crystals on cooling. (Chem. Cent. Blatt, Oct. 21, 1857, p. 766.) The berries are about the size of a pea, red and bitter, and are said to be purgative, emetic, and diuretic. Ten or twelve of them will usually act on the bowels, and sometimes vomit. Their expressed juice has been used in jaundice.

The *Ilex opaca*, or American holly, is a middling-sized evergreen tree, growing throughout the Atlantic section of the United States, and especially abundant in New Jersey. It is so similar to the European plant, that it is, by some writers, considered as the same species. The berries, examined by Mr. D. P. Pancoast, were found to contain tannin, pectin, two crystallizable organic principles, and salts of potassa, lime, and magnesia. One of the crystallizable principles was inodorous and tasteless, the other inodorous but intensely bitter. The latter was obtained by a treatment similar to that of M. Labourdies, above described; but, after the evaporation of the tincture to a syrupy consistence, the process was continued by adding carbonate of potassa and afterwards ether, and agitating briskly. The ethereal solution, rising to the surface on repose, was separated, and allowed to evaporate spontaneously. Crystals of the bitter principle were deposited. This is probably pure illicin. (Am. Journ. of Pharm., xxviii. 314.) This species is said to possess the same medical properties as *I. Aquifolium*.

*Ilex Paraguatensis*, the *I. Mate* of St. Hilaire, yields the celebrated Paraguay tea, so extensively consumed as a beverage in the interior of South America. It is a small tree or shrub growing wild along the streams in Paraguay, and also cultivated for the sake of its leaves, which are the part used. These are stripped from each plant every two or three years. (Parodi, Revista Farmaceutica de Buenos Aires, Jan. 1801.) They have a balsamic odour and bitter taste, and are usually at first disagreeable to the palate. They have a pleasant corroborant effect upon the stomach; but, when very largely taken, are said to purge and vomit. They are used in the form of infusion. According to Stenhouse, these leaves contain a principle identical with the caffein of tea and coffee; and like them contain also tannic acid; so that a close analogy exists in composition as well as effects between these three products, so little allied botanically, and so far separated in place of growth.

The *Ilex vomitoria* of Aiton and Linn., the *I. Cassina* of Michaux, is a handsome evergreen shrub, growing in our Southern States, and especially abundant along the southern coast of Florida. It is the *cassina* of the Indians, who formerly employed a decoction made from the toasted leaves, called black drink, both as a medicine, and as a drink of etiquette at their councils. It acts as an emetic. The leaves of the *Ilex Dahoon* of Walter and Michaux have similar properties, and are also said to have entered into the composition of the black drink.

**ILLICIUM FLORIDANUM.** Florida Anise-tree. This is an evergreen shrub or small tree, growing in Florida, along the coast which bounds the Gulf of Mexico. The bark, leaves, and probably also the seed vessels, are endowed with a spicy odour and taste, analogous to those of anise, and might, perhaps, be used for the same purpose as that aromatic. It is a question worthy of investigation, whether the capsules of this plant might not be substituted for those of the *Ilicium anisatum* or star aniseed, which yield much of the oil used in this country under the name of oil of anise. (See Anisum.) Another species, *I. parviflorum*, a shrub found by Michaux in the hilly regions of Georgia and Carolina, has a flavour closely resembling that of sassafras root.

**IMPATIENS FULVA** and **IMPATIENS PALLIDA.** Touch-me-not. Jewel-weed. Balsam-weed. These two species of Impatiens are indigenous, annual, succulent plants, from two to four feet high, growing in low moist grounds in all parts of the Union, and flowering in July and August. They may be known by their tender, juicy, almost transparent stems; by their yellow flowers, which in one species are pale and sparingly punctate, in the other, are deeper coloured and crowded with dark spots; and by their capsules, which burst elastically, and curl up with the slightest pressure. They probably possess properties similar to those of the *I. Noli-me-tangere* of Europe, which has an acrid burning taste, and, when taken internally, acts as an emetic, cathartic, and diuretic, though considered dangerous, and therefore little used. The late Dr. Ruan, of Philadelphia, informed us that he had employed with great advantage, in piles, an ointment made by boiling the American plants, in their recent state, in lard. The flowers may be used for dyeing yellow. The *I. Balsamina* or balsam-weed, touch-me-not, &c. of the gardens, resembles the other species in its effects.

**IMPATERIA OSTRUTHIUM.** Masterwort. An umbelliferous plant, indigenous in the south of Europe. The root has a strong odour, similar to that of angelica, and a pungent, biting, aromatic taste, attended with a flow of saliva, and followed by a glowing warmth which remains long in the mouth. A crystallizable, tasteless principle, called imperatorin, was extracted from the root by Wackenroder, by allowing the ethereal tincture to evapo-
part, and recrystallizing the residue from ether and alcohol. It was purified by combining it with lime, and decomposing the lime compound by acetic acid. R. Wagner has ascertained that this principle is identical with peucedamin, obtained from the root of Peuce
danum officinale, which was formerly employed in medicine, but is now quite out of use. The principle is composed of carbon, hydrogen, and oxygen, and is probably inert. (Chem.
Gaz., Nov. 1, 1854.) The root of masterwort was formerly considered alexipharmic, sto-
machic, corrodant, emmenagogue, diuretic, and diaphoretic; and was used in a wide circle of complaints with so much supposed success as to have gained for it the title of
divinum remedium. The fact, however, appears to be, that it is merely a stimulant aromatic,
analogous but inferior to angelica, which has nearly superseded it in European practice.
In this country it is unknown as a remedy, and its vulgar name has been applied to
another plant.

INDELIBLE INK. This is prepared by dissolving two drachms of nitrate of silver and
a drachm of gum arabic in a fluidounce of distilled water, coloured with a little Indian ink. It is used for writing with a pen on linen and muslin. The place to be marked is prepared by being moistened with a solution of two ounces of crystallized carbonate of soda and two drachms of gum arabic in four fluidounces of water, and then dried. The alkaline solution decomposes the nitrate, and protects the cloth from the action of the free nitric acid. At the end of 24 hours, the spot is to be washed.

Mr. Redwood, of London, proposes the following indelible ink, not requiring the use of
a mordant. Dissolve an ounce of nitrate of silver, and an ounce and a half of crystallized carbonate of soda, separately, in distilled water, and mix the solutions. Wash the pre-
cipitated carbonate of silver, and, having introduced it, still moist, into a Wedgwood mor-
tar, rub it with eight scruples of tartaric acid, until effervescence ceases. Then add strong solution of ammonia, just sufficient to dissolve the tartrate of silver formed (about two fluidounces). Lastly, having mixed in half a fluidounce of archil, half an ounce of white sugar, and an ounce and a half of powdered gum arabic, add sufficient distilled water to make the whole measure six fluidounces. M. Soubeiran has given the following formula for indelible ink, which he considers simpler than Mr. Redwood’s. Dissolve 8 parts of crystallized nitrate of silver, 3 of nitrate of copper, and 4 of carbonate of soda, in 100 of water of ammonia, and add to the solution a little gum. The marks, produced by nitrate of silver on linen or muslin, may be completely removed by moistening them with a solution of corrosive sublimate in 30 parts of distilled water, and afterwards washing them with ordinary water.

M. Jules Guiller has devised the three following formulas for marking-inks for linen.
1. Nitrate of silver 11 parts; distilled water 85; powdered gum arabic 20; carbonate of soda 22; solution of ammonia 20. Dissolve the carbonate of soda in the water, rubbing the solution with the gum, and the nitrate of silver in the ammonia. Mix the solutions, and gradually heat the mixture in a flask until it boils. This ink flows readily from a pen.
2. Nitrate of silver 5 parts; distilled water 12; powdered gum arabic 5; carbonate of soda 7; solution of ammonia 10. The ingredients are treated as in the preceding formula, with the exception that the mixed solution is heated until it becomes of a very dark colour, and is reduced about one-twentieth in volume by evaporation. This ink is suitable for marking on linen with stamps. 3. Nitrate of silver 17 parts; distilled water 85; powdered gum arabic 20; carbonate of soda 22; solution of ammonia 42; sulphate of copper 33. Dissolve the nitrate of silver in the ammonia, the carbonate of soda in 25 parts of the water, and the gum in the remaining 60. Then mix with the soda solution, first the gum solution, and afterwards the silver solution. Lastly, add the sulphate of copper. This ink has a blue, instead of the dark-brown colour of the others. (See Am. Journ. of Pharm., Jan. 1853, p. 33.)

Herberger recommends the following indelible ink for other purposes than marking
linen. Dissolve wheat gluten, carefully freed from starch, in a little weak acetic acid, and dilute the solution with rain water, so as to have about the strength of wine vinegar. For every four ounces of the solution, add ten grains of the best lampblack, two grains of indigo, and a little oil of cloves. This ink has a beautiful black colour, and cannot be removed by chlorite or dilute acids. (Chem. Gaz., No. 70, p. 394.)

INDIAN RED. A purplish-red pigment, brought from the island of Ormus in the Persi-
ian Gulf. It is a red ochre, and owes its colour to the red oxide of iron.

W.

INDIAN YELLOW. This is a pigment manufactured from a yellow substance from
India, called purree. Purree occurs in commerce in balls, of from three to four ounces in
weight, which are dark-brown externally, and deep-orange within. It has a peculiar
smell, closely resembling that of castor. This circumstance gave rise to the belief that it
was of animal origin; but Dr. Stenhouse, who examined it chemically, finds that it con-
tains no nitrogen, and from this and other facts is led to the opinion that it is a vegetable
substance. Upon analysis he found it to consist of magnesia, united with a peculiar acid,
which he names purreic (euzanthic acid of Erdmann), and which forms nearly one-half of
the crude substance. Purrie acid is in small crystals of a light-yellow colour, dissolving sparingly in cold water, pretty readily in boiling water, and abundantly in hot alcohol. It has at first a sweetish and then a slightly bitter taste, and possesses, in appearance, considerable resemblance to berberina. When acted upon by boiling nitric acid, it is finally converted into a new acid, crystallizing in yellow needles, called by Erdmann, oxypric acid. Purrie acid has the formula C₆H₇O₃N. From his examination of purrie, Dr. Stenhouse concludes that it is probably the juice of some plant, saturated with magnesia, and boiled down to a solid consistence. (See his paper in the Philos. Mag., xxv. 821.) Other authorities conjecture that it is obtained from the deposit of camels' urine, after the animals have eaten the fruit of Mangocinna mangifer. (Chem. Gaz., April, 1855, p. 134.)

INDIGO. This well-known and highly important dye-stuff is obtained from various species of Indigofera, especially I. tinctoria, I. Anil, and I. argentea; and is said to be afforded also by other plants, such as Wrightia tinctoria, Polygonum tinctorium, Gajea tinctoria, &c. It does not exist ready formed, but is generated, during fermentation, from another principle existing in the plant. This principle appears to have been isolated from Isatis tinctoria by Ed. Schunck, who has named it indican. Through the agency of the mineral acids, it is resolved into indigo and sugar; and perhaps the same result may take place in fermentation. Indican is yellow, amorphous, of a nauseous bitter taste, with an acid reaction, and readily soluble in water, alcohol, and ether. It contains nitrogen. (Pharm. Journ., xv. 166.) In the process of preparing indigo, the plant is macerated in water; fermentation takes place; the liquor becomes of a greenish colour, and in due time is decanted; the colouring principle dissolved by the water absorbs oxygen from the air, and assumes a blue colour, becoming at the same time insoluble; a gradual precipitation takes place, favoured by the addition of lime-water or an alkaline solution; and finally the precipitated matter, having been washed upon linen filters, is dried, shaped usually into cubical masses, and sent into market. Most of the indigo consumed in dyeing is brought from the East Indies, though considerable quantities are imported also from Guatemala, and the northern coast of South America. It was formerly produced in our Southern States, especially Florida, where the plant grows luxuriantly; and it still appears to be prepared there for local use. (See Am. Journ. of Pharm., xxvii. 473.) It is of an intensely blue colour, but assumes a coppery or bronze hue when rubbed with a smooth hard body, as the nail. Heated to 550°, it emits a reddish-violet vapour, which condenses in minute crystals. It is insoluble in water or alcohol, but is readily dissolved by sulphuric acid, which, without destroying its blue colour, so far alters its nature as to render it freely soluble in water, and thus affords a convenient method of applying it to the purposes of dyeing. The solution in sulphuric acid is kept in the shops under the name of sulphate of indigo. According to Berzelius, indigo contains, among other ingredients, four distinct principles:—1. a substance resembling gluten; 2. a brown colouring substance; 3. a red colouring substance; and 4. a blue colouring substance, which is the principle upon which its value as a material for dyeing depends, and which seldom constitutes so much as one-half of the indigo of commerce. This blue colouring matter is called indigotin. By deoxidizing agents it is deprived of its blue colour, which it recovers by exposure to the air, in consequence of the absorption of oxygen. Such is the case with the acid sulphites, and in a less degree with sulphuric acid. Certain volatile oils are said to have the same effect when boiled with tincture of indigo, as the oil of turpentine, peppermint, lavender, juniper, savine, or sage. (Journ. de Pharm., Nov. 1859, p. 399.) Chlorine also destroys the blue colour. M. Preisser has concluded, from an elaborate examination of the colouring principles of plants, 1. that these principles are colourless in the young plants; 2. that they acquire colour by combination with oxygen; 3. that all the colouring matters, extracted from any one plant, are produced by the oxidation in different degrees of a single principle; 4. that they are deprived of colour by substances having a strong affinity for oxygen, and reacquire it by contact with oxidizing bodies; and 5. that these colouring principles are acids, and the lakes which they form genuine salts. (Journ. de Pharm., 5e sér., v. 263.) For modes of testing the value of any specimen of indigo, see the Chemical Gazette (vii. 463, viii. 448, and x. 169); the Chem. News (Dec. 12, 1862, p. 284); and the Am. Journ. of Pharm. (xxv. 228).

Indigo has been proposed by E. Mulder as a test for glucose and fruit sugar, which have the property of changing the blue colour of indigo to white in the presence of the alkalies. To the solution to be examined he adds sulphate of indigo, previously treated with an excess of carbonate of potassa or soda. The addition of the carbonated alkali to the sulphate of indigo scarcely affects the blue colour even at a boiling heat; but if the solution contain glucose or fruit sugar, the blue colour disappears even in the cold, but more rapidly with heat. Common sugar has no such effect. (Journ. de Pharm., Sept. 1860, p. 179; from Archiv. der Pharm., clv. 268.)

Indigo has been introduced to the notice of the profession as a remedial agent. It was at first employed chiefly by the German physicians, from whose statements our knowledge of its physiological action and therapeutical application was derived. Though without odour and taste, it is said, in most individuals, to produce nausea and vomiting, frequently to ope-
PART III.  

Insect Powder.—Iodide of Ammonium.  153

rate upon the bowels, giving a bluish-black colour to the stools, to render the urine of a dark-violet or dark-green colour, without increasing its quantity, and sometimes to stimulate the secretory function of the uterus. From these statements it would appear to act as an irritant to the alimentary mucous membrane. The character of its general influence upon the system has not been well ascertained. In some instances, it is asserted to have been given in very large doses without any obvious effect. In connection with its influence, the curious fact may be stated, that a colouring matter has been occasionally found in the urine, either spontaneously deposited, or separated by the addition of strong muriatic acid, which in colour and other properties, especially that of being sublimable, bears a close resemblance to indigo, if it be not identical with it. (Chem. Gaz., July 15, 1854, p. 267.) The complaints in which indigo has been employed, with supposed advantage, are epilepsy, infantile convulsions, chorea, hysteria, and amenorrhea. It is given, usually in connection with some aromatic powder, in the dose of a scruple three times a day, which may be increased to a drachm or more; and from half an ounce to an ounce has been employed daily for months together without disadvantage. (See Am. Journ. of Med. Sci., xx. 457.) The general failure of indigo to produce the desired effects in epilepsy, in which it had at one time considerable credit as a remedy, has been ascribed to the use of too small doses. M. Ideler, of Berlin, began with about two drachms daily, and increased gradually to two ounces; but there was great difficulty in reconciling the patient to such doses, on account of the intense nausea produced. (B. and P. Medico-Chirurg. Rev., Am. ed., Jan. 1856, p. 198.) W.

INSECT POWDER. Under the name of Persian or Caucasian Insect powder, a substance has recently attracted attention in Western Europe, which has long been in extensive use among the people of Western Asia and Eastern Europe, for the destruction of vermin. Among the people south of the Caucasus, it is called guirila. It consists of the flowers of the Pyrethrum cuneum, and P. roseum, growing upon the Caucasian mountains, at an elevation of about a mile. It is a coarse powder, of a greenish colour, and pungent odour. It does not appear to be poisonous to man, though it is said to cause some confusion of head in those who sleep in close apartments where much of it is used. Upon the insects, however, which are apt to infest the person of man and animals, as well as bedding and sleeping apartments, it acts very destructively, first stupefying and then killing them. It is scattered over the person, upon the beds, about apartments, &c., and is even employed as a dressing for ulcers and wounds to prevent the formation of maggots. It also answers to preserve dried insects and plants in cabinet collections. The demand for the powder having much increased of late, it is said to be adulterated with the leaves and stems of the plant. (Noodt, Buchner’s Neues Report., vii. 562.) W.

IODATE OF POTASSA. This salt has been proposed as a substitute for the chlorate of potassa. MM. Demarquay and Custin propose the following mode of preparation. Take of iodine and chlorate of potassa, each, one part, and mix them with five or six parts of water, previously acidulated with a few drops of nitric acid, and heated to ebullition. As soon as chlorine ceases to escape, treat the liquid with a concentrated solution of chloride of baryum. Wash with distilled water, and decompose with dilute sulphuric acid the iodate of baryta precipitated; filter to separate the sulphate of baryta; and slowly evaporate the solution. Wash with distilled water the crystals of iodic acid that are formed, dissolve them in boiling distilled water, and saturate with bicarbonate of potassa. On cooling, the iodate is deposited in small crystals. The authors above mentioned have employed the iodate of potassa in all those cases of ulcerated and otherwise diseased mucous membrane of the mouth and fauces, in which the chlorate is usually prescribed, and have found it to produce the same curative effects more quickly, more energetically, and in smaller dose. In the healthy state, it acts remarkably on the pharyngeal and buccal mucous membrane, producing, in the quantity of 20 or 30 grains, a peculiar sense of constriction, and appearing considerably to diminish the mucous secretion. The diseases in which they have found it specially beneficial are diphtheria, mercurial affection of the mouth, and gangrenous stomatitis. The dose used by them was from four to eight grains. (Dorval’s Rev. Pharm., 1858, p. 25.) W.

IODIDE OF AMMONIUM. Ammonii Iodidum. Hydriodate of Ammonia. This salt is prepared in the following method by Mr. John A. Spencer, of London. Add to a portion of iodine, placed in a flask with a little water, a solution of hydro sulphuret of ammonia, until the mixture loses its red colour, and is turbid from the separation of sulphur only. Shake the flask, which causes the sulphur, for the most part, to agglomerate; and, having poured off the liquid, boil it until all odour of sulphuretted hydrogen and of ammonia is lost. Then filter the liquid, and, constantly stirring, evaporate it, first with a naked flame until it becomes pasty, and then in a water-bath until it forms a dry salt. Dr. Jacobson prepares the salt by dissolving equiv. weights of pure iodide of potassium and pure sulphate of ammonia, severally, in the smallest quantity of boiling distilled water, mixing and stirring the solutions, and, after the liquid has cooled, adding water containing 15 per cent. of alcohol, and setting it aside for 12 hours. Sulphate of potassa is
Iodide of Antimony.—Iodide of Sodium.

PART III.

Iodide of Antimony. Antimonii Iodidum. Teriodide of Antimony. According to Mr. W. Copney, of London, this iodide may be conveniently prepared by gently heating, in a Florence flask, metallic antimony and iodine, in the proportion of one eq. to three. The elements combine with the formation of a diiodide of antimony, and the withdrawal of the heat will give formed solidifies, and is removed from the vessel by breaking it. Iodide of antimony, as thus prepared, forms a somewhat crystalline, foliated mass, which, when pulverized, yields a deep orange-red powder. By the action of water it is decomposed. It has been tried as an alternative in a dose varying from a quarter of a grain to a grain, given in the form of pill.

Iodide of Barium. Barii Iodidum. This compound may be formed by double decomposition, by adding native carbonate of baryta in powder to a boiling solution of iodide of iron. M. Henry, jun., obtained it by decomposing a solution of sulphuret of barium (see page 1022) by a concentrated alcoholic solution of iodine. Sulphur is precipitated, which is separated by filtration, and iodide of barium formed in solution, from which it is obtained in the solid state by rapid evaporation to dryness. Iodide of barium crystallizes in rhombohedra, which deliquesce slightly, and are very soluble in water. The solution promptly undergoes decomposition by exposure to the air, carbonate of baryta being precipitated, and iodine set free, which colours the solution. It has been used with advantage by Jahn, as an alterative, in scrofulous affections and morbid growths. Lugol employed it in scrofulous enlargements. The dose is the eighth of a grain three times a day, gradually increased to three grains. Biett applied it to scrofulous swellings in the form of ointment, made with four grains of the iodide to an ounce of lard.

Iodide of Silver. Argenti Iodidum. This compound is formed by double decomposition, by adding a solution of iodide of potassium to one of nitrate of silver. It is a granish-yellow powder, nearly insoluble in amonia. It possesses the general medical properties of nitrate of silver, and, according to Dr. Charles Patterson, of Dublin, may be used without any danger of producing the discoloration of skin which sometimes follows the use of that salt. Dr. Patterson found it generally successful in curing the stomach affections of the Irish peasantry, in the treatment of which nitrate of silver had previously proved useful. He succeeded with it in curing several cases of hooping-cough in a short time, and in greatly relieving a case of dysmenorrhea of three years’ standing. Its effects in epilepsy were least satisfactory. The dose is one or two grains, three times a day, given in the form of pill; for children, from the eighth to the fourth of a grain, according to the age.

Iodide of Sodium. Solit Iodidum. This iodide may be prepared either by saturating a solution of caustic soda with iodine, or by double decomposition between iodide of iron and carbonate of soda, precisely as iodide of potassium is obtained by the corresponding processes for that salt. (See page 1296.) As only small quantities are likely to be wanted as a medicine, the latter process is preferable; being more easily conducted on a small scale. It is a very soluble white salt, crystallizing in anhydrous cubes from a hot solution, and in oblique rhombic prisms, with four eqs. of water, by spontaneous evaporation. Iodide of sodium has the same therapeutic effects, and is used in the same diseases as iodide of potassium. It is said to be better borne than the latter iodide. In Italy it has been used
with remarkable success in constitutional syphilis. The dose is twenty grains, gradually increased to forty, three times a day, dissolved in three fluidounces of water. (See Prof. Procter's paper on the preparation of this iodide, in the Am. Journ. of Pharm., July, 1854, p. 305.)

IODIDE OF STARCH. Dr. Andrew Buchanan, of Glasgow, proposed this compound as a means of administering iodine in large doses without causing irritation of the stomach. He prepares it by triturating twenty-four grains of iodine with a little water, adding gradually an ounce of very finely powdered starch, and continuing the trituration until the compound assumes a uniform blue colour. The iodide is then dried by a gentle heat, and kept in a well-stopped bottle. The dose is a heaped teaspoonful, given in water, three times a day, and afterwards increased to a tablespoonful. No nicety is necessary in apportioning the dose. In some cases Dr. Buchanan has given half-ounce doses of the iodide three times a day, immediately increased to an ounce. Thus administered iodine produces, according to this writer, little or no irritation of the alimentary canal, but is freely absorbed, as is proved by its detection in large quantity in the secretions. Dr. Buchanan thinks that, by means of the starch, the iodine is converted into hydriodic acid, and in this state enters the circulation. Prof. John C. Dalton, of New York, found that nearly all the animal fluids decompose iodide of starch, and destroy its blue colour. (Am. Journ. of Med. Sci., April, 1856, p. 327.) This result is owing, no doubt, to the alkaline nature of most of the animal fluids, especially those of the duodenum. The iodine, being saturated with the alkali of the fluids, is no longer in the free state, the condition necessary to enable the starch to form the blue compound with it. In other words, the starch compound is decomposed, and the starch set free. He prefers the iodide of starch to any other preparation of iodine for obtaining the alterative apart from the irritant effects of this substance. (Ibid., xx. 213 and 217.) See Diluted Hydriodic Acid, page 922.

It is a point of importance to have the iodide of starch soluble in water. M. Magnes-Lahens, of Toulouse, gained this advantage by his original process of roasting the starch moderately, whereby it is converted into dextrin, before it is mixed with the iodine. Subsequently he abandoned the use of torrefied starch, and now contents himself with making an intimate mixture of iodine and starch, slightly moistened, which he subjects to the heat of a water-bath, until it is converted into the iodide of starch, forming a solution with water of a magnificent blue colour. The heat, thus regulated, disaggregates the starch, without completely transforming it into dextrin, and gives a preparation, in the form of a black powder, resembling the soluble iodide of starch, prepared by M. Queeneville by a secret process. M. Sepult, of Constantinople, has also given a formula for this soluble iodide, and for a syrup to be made from it. (See Journ. de Pharm., Mars, 1852, p. 202.) M. Soubeiran reported upon these preparations to the Paris Society of Pharmacy, and deemed them injurious on account of their variable strength in iodine, arising from the greater or less loss of this element during the necessary exposure to heat. Nevertheless, as the syrup is called for, he recommended the following process for making it, availing himself of the observations of his predecessors, which he had occasion to cite in his report. The quantities of the ingredients are here stated in French grammes, each of which weighs about fifteen grains. Triturate thoroughly, in a porcelain mortar, 36 grammes of nitric starch with 42 grammes of iodine, dissolved in three times its weight of ether, and added in successive portions, until, after the evaporation of the greater part of the ether, a blue powder remains. Introduce this into a weighed, stoppered flask, and, having added 520 grammes of water, expose the whole to the heat of a water-bath, with the stopper at first removed, in order to complete the dissipation of the ether. Afterwards the stopper is replaced, being loosely tied with a packthread, so as to permit of its being raised without being driven out: and the heat is continued for about an hour and a half, when the iodide of starch will be completely formed. The flask is then weighed, and a quantity of water added to it, equal to that lost by evaporation. Lastly, 1040 grammes of sugar are added to the liquid, and dissolved by a gentle heat. By this formula a syrup is prepared, containing a quarter of one per cent. of iodine, a small part of which is in the state of hydriodic acid. The nitric starch is used by M. Soubeiran, because it unites with the iodine in much less time than the ordinary starch. It is made by mixing ordinary starch, in the cold, with 150 parts of water, to which 1 part of nitric acid has been added, and allowing the whole to dry in the open air. Three grains of this syrup, diluted with a pint of water, communicate to the liquid a sensible blue tint. This test may serve to determine whether the preparation is of full strength. (Journ. de Pharm., May, 1852, p. 829.) The dose of the syrup is from one to four tablespoonsfuls a day.

IODIDE OF ZINC. Zinci Iodidum. This iodide may be formed by digesting an excess of zinc, in small pieces, with iodine diffused in water. Combination takes place, and, by evaporation, a deliqueuscent, very soluble saline mass is obtained, having a metallic styptic taste, resembling that of sulphate of zinc. It may also be obtained by heating in a mortar a mixture of 20 parts of zinc and 170 of iodine, and subliming into a vial. When thus pre-
Iodo-chlorides of Mercury.—Iodoform.

PART III.

pared, it is in the form of white needles. This salt is very liable to undergo spontaneous decomposition.

Iodide of zino is tonic, astringent, and antispasmodic. In 1853, Dr. Barlow tried it in Guy’s Hospital, in cases of chorea, scrofula, cachexia, and some forms of hysteria, with favourable results. (Med. Times and Gaz., Nov. 1853, p. 501.) Since then a further experience has confirmed his first estimate of its value. He considers it particularly applicable to the treatment of chorea, when complicated with scrofula. (Ibid., August, 1857, p. 195.) The best form of administration is syrup, to protect it from change, originally proposed by the late Dr. A. T. Thomson, and made on the same plan as the syrup of iodide of iron. (See page 1309.) Mr. A. B. Taylor, of Philadelphia, proposes to form it by gently heating, in an evaporating dish, twelve drachma and two scrupules of iodine, and an ounce of finely granulated zinc, with nine fluidounces of water, until they unite, filtering the solution, while hot, on a pound (avoiding.) of sugar, contained in a wide-mouthed bottle holding a little more than a pint, and adding, through the filter, sufficient water to make the whole measure a pint. This syrup is perfectly clear and colourless, is styptic to the taste, and contains a drachm of iodide of zinc in each fluidounce. (Am. Journ. of Pharm., Jan. 1852, p. 38.) The dose of this syrup is from 20 to 60 drops, sufficiently diluted with water, three times a day.

Iodide of zinc has been used for many years as an external application. Dr. J. J. Ross, of Scotland, employed a solution, containing from 10 to 30 grains to the fluidounce of water, with great advantage in enlarged tonsils, applied by means of a piece of sponge tied to a quill. After the use of the solution for some time, he applied the iodide, rendered liquid by dilution, as a unction. A solution containing one or two grains to the fluidounce of water has been used as an antiseptic injection in gonorrhoea. An ointment made with a drachm of the iodide to an ounce of lard, has been substituted by Dr. Urc for the treatment of iodide of potassium in the treatment of tumours, applied in the quantity of a drachm twice a day.

IODO-CHLORIDES OF MERCURY. Iodides of Calomel. These compounds, called subiodide and protiodide of calomel, were brought forward as remedies by M. Boutigny in 1847. To prepare the former, one eq. of iodine and two eqs. of calomel are taken; the calomel is introduced into a matras, and gradually heated, with agitation, till it begins to sublime; then the iodine is added in small quantities at a time. The combination takes place with some sound, but without sensible loss of iodine. The second compound is prepared in the same mode precisely, one eq. of calomel only being used. (Arch. Gén., Janv. 1857, p. 91.) M. J. Perrenais proposes to make them, without the assistance of heat, by rubbing up, in a mortar, the constituents, taken in the proper equivalent quantities. Though called iodides of calomel, the protiodide is a mixture or combination of biniiodide and bichloride of mercury, and the subiodide the same, with an excess of calomel. Both these substances are active preparations, and have been employed with success in syphilis, scrofulous, and cancerous affections. The subiodide may be given in pill, in the dose of the twenty-fifth of a grain. The ointment is formed of one part of the subiodide to eighty of lard. It has been used by M. Rochard with advantage in acne rosacea, applied by daily friction, and as a local application in engorgements of the neck of the uterus. The protiodide is used externally only, and should be applied with caution. It acts as a caustic, and may be cast into sticks, like nitrate of silver. An ointment may be made of it, by rubbing one part with twenty of fresh lard. A portion of the ointment, the size of a large pea, may be rubbed daily on a scrofulous tumour, in the armpits, or on the inner part of the thigh.

IODOFORM. Iodoformum. Teriodide of Formyl. (C₃H₇I₃.) This compound, discovered by Sthrullas in 1822, was introduced as a remedy, about the year 1837, by Dr. R. M. Glover, of London, and M. Bouchardat, of Paris. It may be obtained, according to the process of MM. Cornélias and Gille, of Liiez, by adding to an alcoholic solution of iodide of potassium, heated to 104°, chlorinated lime, in successive portions, mixing after each addition, until the liquid ceases to assume a dark-red colour. On cooling a confused mass of crystals is deposited, consisting of iodoform and iodate of lime. By treating these with boiling alcohol of 90 per cent., the iodoform alone is dissolved; and the alcoholic solution, as it cools, deposits the iodoform in crystals. (Journ. de Pharm., Sept. 1852, p. 196.) It is in the form of small, pearly, yellow crystals, having a strong saffron-like odour, and sweet taste, insoluble in water, but readily soluble in alcohol and ether. It is a volatile substance, soft to the touch, and totally devoid of corrosive properties. Given to the inferior animals it destroys them in a smaller dose than iodine does, producing depression, followed by a stage of excitement, with convulsions, contractions, &c. Though containing 29 parts in 100 of its weight of iodine, it has not the least local irritant action. In the form of vapour, it possesses anaesthetic properties, but inferior to those of chloroform. On account of its large proportion of iodine, it is supposed to be capable of replacing that element and the iodides as a remedy, with the advantages of being non-irritant, and of having an organic nature, qualities which favour its absorption and assimilation. Besides the virtues it possesses in common with iodine, it is capable of acting as an anodyne, and is useful in neuralgic affections. The principal diseases in which it has been tried are goitre, rickets, scrofula,
PART III.

Iodohydrargyrate of Potassium.

1541

phthisis, amenorrhœa, syphilis, glandular tumours, and cutaneous eruptions. In chronic enlargements of the prostate gland, M. Moret in recommends the employment of iodiform as a suppository, made of a scruple of iodiform to an ounce of cocoa butter. The dose of iodiform is from one to three grains, three times a day, given in the form of pill. In the treatment of cutaneous diseases and tumours, it is applied in the form of ointment, made by mixing from half a drachm to a drachm with an ounce of lard.

B.

IODOHYDRARGYRATE OF POTASSIUM. It has been found by chemists that different iodides will unite together in different proportions, forming compounds which are called by Berzelius double iodides. Bonsdorff, of Finland, and Dr. Hare, of this city, with greater reason, have viewed these combinations as a peculiar kind of salts, in which one of the iodides performs the part of an acid, the other of a base. The substance, the name of which is placed at the head of this article, is one of these compounds, and was presented to the notice of the profession, as a new remedy of remarkable powers, in February, 1834, by Dr. William Channing, of New York. (Am. Journ. of Med. Sci., xiii. 388.) It consists of biniodide of mercury acting as an acid, and iodide of potassium as a base. But as these iodides combine in at least two proportions, it is necessary to indicate the particular combination employed by Dr. Channing.

In a difficult case of pectoral disease, in which the ordinary remedies had failed, Dr. Channing determined to trial one of the iodides of mercury. He selected the biniodide; and, in order to have it in the liquid form, as it is insoluble in water, he dissolved it in a solution of the iodide of potassium. He was struck with the peculiar changes which the compound solution underwent; and, on pursuing his observations, found that the two iodides really united by the intervention of the water; for, with the aid of an operative chemist, he was enabled by evaporation to obtain them in union, in the form of straw-coloured, needleform, deliquescent crystals. He next found, upon consulting the European authorities, that Bonsdorff, who had taken the lead in investigating similar compounds, had discovered the salt in 1826.

Dr. Channing analyzed the salt with which he experimented, and found that it consisted of one eq. of biniodide of mercury, and two of iodide of potassium. This he determined by ascertaining that an aqeous solution of a little more than eight grains of iodide of potassium would dissolve, and combine with, eleven grains of biniodide of mercury, without being liable to decomposition when largely diluted with water. The combination here indicated corresponds with one of the double iodides of mercury and potassium, described by Thenard. (Traité de Chimie, 6ème ed., iii. 493.) The other is represented by this author as consisting of a single eq. of each iodide. When copiously diluted with water, every two eqs. of this iodide let fall one eq. of the mercurial iodide; thus converting the salt into the medicinal double iodide. The same decomposition by means of water is noticed by Dr. Channing. For remarks on these double iodides see a paper by Mr. Ambrose Smith, Am. Journ. of Pharm. (xii. 265.)

Dr. Channing attributes to this preparation the effects of diffusing excitement, and equalizing the circulation. In the different cases in which he tried it, he thought he saw evidence of its favourable influence on the lungs, in allaying cough and improving expectoration; on the alimentary canal, in restoring the healthy secretions; on the kidneys, in reviving their activity; on the skin and cellular tissue, in cicatrizing superficial ulcerations; and on the absorbent and exhalant systems, in causing the disappearance of effused fluid. The principal diseases in which he found it useful were chronic bronchitis, hooping cough, tonsillitis, chronic gastro-enteritis, dyspepsia, ascites, anasarca, amenorrhœa, leukorrhœa, eruptions, and scrofula. In some cases of phthisis, it mitigated the symptoms, and appeared to prolong life. Dr. Hildreth, of Ohio, has tried the preparation, and reports favourably of its effects in functional dyspepsia, enlargement of the spleen, amenorrhœa, dysmenorrhœa, leukorrhœa, scrofulous affections, ascites, and general dropsy. (Am. Journ. of Med. Sci., xxvi. 312.)

The average dose of the remedy may be stated at the twelfth of a grain three times a day; but in peculiar constitutions, not more than the forty-eighth, the ninety-sixth, or the two hundredth of a grain daily can be borne. For the convenience of physicians who may wish to make trial of the remedy, we give the following formula, deduced from the statements in Dr. Channing's paper.—Take of iodide of potassium three and a half grains; biniodide of mercury (red iodide) four and a half grains; distilled water a fluidounce. Dissolve first the iodide of potassium and then the biniodide of mercury in the water. The compound salt in this solution may be assumed to amount to eight grains, though there is a small excess of the iodide of potassium. Of this solution, from two to five drops, containing from the thirtieth to the twelfth of a grain, may be given three times a day. It may be administered in the compound syrup of sarsaparilla, which does not decompose it.

B.

The iodo-hydrargryrate of potassium was suggested by F. L. Winckler as a qualitative test of the organic alkaloids, with which it produces insoluble precipitates; and subsequently it has been used by Prof. F. P. Mayer, of New York, for determining the quantity of these alkaloids in any mixture containing them. Prof. Mayer employs, for volumetric analysis, a solution made with 13-546 grammes of corrosive sublimate, 49-8 grammes of iodide of po-
This page contains a discussion on the properties of certain plants and their alkaloids, including:

The text includes various chemical analyses and references to published works, indicating a scientific approach to the study of these natural substances.
PART III.

Jellies.—Labdanum.

Jellies. The form of Jelly is sometimes a convenient method of administering medicines, especially the fixed oils, as cod-liver oil and castor oil, which are thus rendered less adhesive to the mouth and fauces, and less liable to leave that disagreeable impression on the palate behind them, which renders such medicines often so offensive that it becomes difficult to administer them. While preparing the jelly, opportunity is also offered for incorporating sugar and aromatics so as very much to cover the offensive taste and odour of the oil. The same remarks are applicable to the resinous juices, as copaiba and some varieties of turpentine, liquid balsam of tolu, &c. The following is a formula recommended by Messrs. Ed. Parrish and Wm. C. Bakes. “Take of the fixed oil or liquid resin a troy ounce; honey, syrup, each, half a troy ounce; gum arabic, in powder, two drachms; Russian isinglass forty grains; orange-flower water six fluidrachms. Dissolve the isinglass, with the aid of heat, in half a fluidounce of the orange-flower water, replacing the water as it evaporates. Triturate the other ingredients, with the remainder of the orange-flower water, into a homogeneous mass in a warmed mortar, then add the hot solution of isinglass, stir the mixture as it cools, and set it aside to gelatinize.” (Am. Journ. of Pharm., Jan. 1861, p. 4.) Any other aromatic water may be substituted for that of the orange-flower, and cinnamon water diluted with an equal measure of pure water would probably better cover the offensive taste. In reference to cod-liver oil, the bitter-almond or cherry-laurel water would be still more effectual; care, however, being taken in this case, that the water is duly diluted, lest too large a dose of it might be administered.

W. KALMIA LATIFOLIA. Laurel. Mountain Laurel. Broad-leaved Laurel. Calico-bush. This well-known evergreen inhabits all sections of the United States, being especially abundant on the sides of hills and mountains, which it adorns in summer with its elegant flowers. It is from three to ten feet in height. The leaves are possessed of poisonous, narcotic properties, and have been used in medicine. They have been analyzed by Mr. Charles Bullock, of Philadelphia, and found to contain gum, tannic acid, resin, chlorophyll, fatty matter, a substance resembling mannite, an acid principle, wax, extractive, albumen, yellow colouring matter, lignin, and salts of potassa, lime, and iron. (Am. Journ. of Pharm., xx. 264.) They are said to prove fatal to sheep and some other animals, but are eaten with impunity by deer, goats, and partridges. Dr. Barton states, in his “Collections,” that the Indians sometimes use a decoction of the leaves to destroy themselves. It is said that death has been occasioned by eating the flesh of partridges and pheasants which have fed upon them during winter. Dr. N. Shoemaker published, in the North American Medical and Surgical Journal, two cases of poisoning which resulted from eating a pheasant, in the claw of which laurel leaves were found. The symptoms were nausea, temporary blindness, pain in the head, dyspnoea, pallid countenance, cold extremities, and a very feeble pulse, which in one case was for some time absent at the wrist, in the other heat only forty strokes in the minute. In both cases relief was afforded by vomiting, produced by a tablespoonful of flour of mustard mixed with warm water. A case of similar poisoning is related in the Edinburgh Medical Journal (May, 1856, p. 1014), in which epigastric tension and uneasiness, glowing heat of the head, loss of sight, coldness of the extremities, general prostration, and twitches of the muscles were the prominent symptoms, followed by nausea and full vomiting, which afforded some relief. But feelings of formication and weakness of the limbs, with great prostration of the circulation, remained for several hours, requiring the use of stimulants.

Dr. Barton was informed that the powdered leaves were employed by an empiric with success in certain stages of fever; and Dr. Thomas, in an inaugural dissertation, published at Philadelphia, A. D. 1802, states that an obstinate case of diarrhœa was cured by a decoction, made by boiling an ounce of the leaves in eight ounces of water down to four ounces. Thirty drops were given six times a day; but this quantity produced vertigo, and the dose was afterwards repeated only four times daily. The leaves are said to have been used advantageously in syphilis. Externally applied, in the shape of ointment or decoction, they have been found useful in tinea capitis, psora, and other cutaneous affections; but caution is necessary in their application, as, according to Dr. Barton, nervous symptoms have resulted from the external use of the decoction. Dr. Bigelow has seen the recently powdered leaves given in doses of from ten to twenty grains, without perceptible effect.

It is probable that other species of Kalmia, as K. angustifolia or sheep-laurel, and K. glauca or swamp-laurel, have properties identical with those of K. latifolia. A decoction of the leaves of K. angustifolia is used by the negroes of North Carolina as a wash for an ulcerative affection between the toes.

W. LABDANUM. Labdanum. A resinous substance, obtained from various species of Cistus, especially C. Creteicus, C. ladaniferus, and C. laurifolius, small evergreen shrubs, inhabiting the islands of the Grecian Archipelago, and the different countries bordering on the Mediterranean. Upon the leaves and branches of these shrubs a juice exudes, which is collected by means of an instrument resembling a rake, with leather thongs instead of teeth, which is drawn over the plant. The juice adheres to the pieces of leather, and is afterwards separated. It is said that labdanum was formerly collected by combing the beards of goats.
Labdanum.—Lac.

PART III.

which had been browsing upon the leaves of the cistus; and Landerer states that it is at the present time gathered in the same way in Cyprus from sheep, whose fleeces become loaded with it while they are pasturing. (See Pharm. Journ., xi. 6.) It comes chiefly from the Grecian Islands. Two varieties exist in commerce. The purest labdanum is in masses of various sizes, sometimes weighing several pounds, enclosed in bladders, dark-red almost black externally, grayish internally when first broken, of the consistence of a plaster, softening in the hand and becoming adhesive, of an agreeable balsamic odour like that of amber, and of a bitter, balsamic, somewhat acid taste. It is very inflammable, burning with a clear flame. On exposure it becomes dry, porous, and brittle. Little of this variety is found in the markets. Common labdanum is in contorted or spiral pieces, light, porous, blackish-gray, hard and brittle, not softening between the fingers, similar in odour and taste to the preceding variety, but less inflammable, and mixed with sand and other earthy matters, which are obvious to the sight. A specimen exhibited at the International Exhibition of 1862, at London, was in flatish pieces, an inch or more thick, with remains of leaves on one side, of a very dark greenish-brown colour, and a granular somewhat shining fracture. Guibourt found in 100 parts of the labdanum in masses, 86 parts of resin with a little volatile oil, 7 of wax, 1 of watery extract, and 6 of earthy substances and hair. In the contorted variety, Pellietier found 20 per cent. of resin, 3 of gum with malate of lime, 0 of malic acid, 1-9 of wax, 1 of volatile oil including loss, and 72 of ferruginous sand.

Labdanum is a stimulant expectorant, and was formerly given in catarrhal and dysenteric affections. At present it is employed in plasters, but seldom even for that purpose in the United States. It is sometimes used in fumigation.

W.

LAC. A resinous substance obtained from several trees growing in the East Indies, particularly from Croton lacciferum, and two species of Ficus, F. religiosa, and F. Indica. It is found in the form of a crust, surrounding the twigs or extreme branches, and is generally supposed to be an exudation from the bark, owing to the puncture of an insect, belonging to the genus Coccus, and denominated C. Lacca. By some it is thought to be an exudation from the bodies of the insects themselves, which collect in great numbers upon the twigs, and are embedded in the concreted juice, through which the young insects eat a passage and escape. Several varieties are known in commerce. The most common are stick-lac, seed-lac, and shell-lac.

Stick-lac is the resin as taken from the tree, still encrusting the small twigs around which it originally concreted. It is of a deep reddish-brown colour, of a shining fracture, translucent at the edges, inodorous, and of an astringent, slightly bitterish taste. Its external surface is perforated with numerous minute pores, as if made by a needle; and when broken it exhibits many oblong cells, often containing the dead insect. When chewed it colours the saliva beautifully red, and, when burnt, diffuses a strong, agreeable odour. It is in great measure soluble in alcohol.

Seed-lac consists of minute irregular fragments, broken from the twigs, and partially exhausted by water. It is of a light or dark-brown colour, inclining to red or yellow, feebly shining, almost tasteless, and capable of imparting to water less colour than the stick-lac, sometimes scarcely colouring it at all. It is occasionally mixed with small fragments of the twigs.

Shell-lac is prepared by melting the stick-lac or seed-lac, previously deprived of its soluble colouring matter, straining it, and pouring it upon a flat smooth surface to harden. It is in thin fragments of various sizes, from half a line to a line thick, often somewhat curved, of a lighter or darker brown colour inclining more or less to red or yellow, shining, more or less transparent, hard and brittle, inodorous and insipid, insoluble in water, but easily and almost entirely soluble in alcohol, especially with the aid of heat. According to Oberdörffer, cold ether takes from shell-lac only about 5 per cent., consisting of wax; and adulteration with resins soluble in ether is thus readily detected. (See Am. Journ. of Pharm., July, 1891, p. 313.)

A variety of lac is mentioned by writers in the form of cakes, called cake-lac or lump-lac (lacces in placenta); but this is at present rare in commerce.

According to John, lac consists of resin, colouring matter, a peculiar principle insoluble in alcohol, ether, or water, called lacin, a little wax, and various saline matters in small proportion. The resin, according to Unverdorben, consists of several distinct resinous principles differing in their solubility in alcohol and water. The lacin is nearly or quite wanting in shell-lac, which also contains scarcely any of the colouring principle. Mr. Hatchett found in stick-lac 68 per cent. of resin, and 10 of colouring matter; in seed-lac 88-6 per cent. of resin, and 2-5 of colouring matter; in shell-lac 90-9 per cent. of resin, and 0-5 of colouring matter. The other constituents, according to this chemist, are wax and gluten, besides foreign matters.

Lac in its crude state is slightly astringent, and was formerly used in medicine; but at present it is not employed. Shell-lac is wholly inert. Stick-lac and seed-lac are used on account of the colouring principle which they contain. Shell-lac, as well as the other
varieties deprived of their colouring matter, is applied to numerous purposes in the arts. It is the chief constituent of sealing wax. The best red sealing wax is made by melting together, with a very gentle heat, 48 parts of shell-lac, 19 of Venice turpentine, and 1 of balsam of Peru, and mixing with the melted mass 32 parts of finely powdered cinnabar. But common resin is often substituted in part for the lac, and a mixture of red lead and chalk for the cinnabar. The best black sealing wax consists of 60 parts of lac, 10 of turpentine, and 30 of levigated bone-black; the best yellow sealing wax, of 60 parts of lac, 12 of turpentine, and 24 of chromate of lead. (Berzelius.) Lac is also used as a varnish, and forms an excellent cement for broken porcelain and earthenware. It has been highly recommended as an adhesive material for the dressing of wounds, ulcers, &c. It is prepared for use by dissolving, with the aid of a gentle heat, in alcohol contained in a glass bottle, sufficient lac to give it a gelatinous consistency, and then closing the bottle. It is used by simply spreading it on the bandages.

W.

LACTATE OF ZINC. Zincli Lactas. This salt may be prepared by first obtaining lactate of potassa by double decomposition between lactate of lime and carbonate of potassa, and then adding the solution of the alkaline lactate, filtered from the carbonate of lime, to one of acetate of zinc. By a new double decomposition, lactate of zinc, on account of its sparing solubility in cold water, is deposited in crystals, and acetate of potassa remains in solution. The crystals may be purified by dissolving them in boiling water, and recrystallizing. This salt is in the form of white plates, soluble in sixty parts of cold water, and six at the boiling temperature. It is insoluble in alcohol. Its taste is highly saccharine, with a styptic after-taste. Exposed to heat it bears a temperature of 392° without decomposition.

Lactate of zinc has been brought forward by M. Herpin as a remedy in epilepsy; and, after a trial of it in this disease for nearly two years, he concludes that it is at least as efficacious as the oxide, with the advantages of being better borne, and more easily taken. The dose is two grains three times a day, given in pill, and gradually increased until it amounts to ten grains. The best time for taking it is about an hour after meals. In M. Herpin's cases it was continued for from five to twelve months.

D.

LAKES. These are compounds of vegetable or animal colouring principles with alumina or other metallic oxide, and are usually obtained by adding alum or bichloride of tin to the solution of the colouring matter in water, and precipitating by means of an alkali. The alumina or oxide of tin unites with the colouring matter at the moment of separation, and forms an insoluble compound. Lakes are obtained in this way from cochineal, madder, Brazil wood, seed-lac, French berries, &c. They are used in painting.

W.

LAURUS NOBILIS. The Bay Tree. The fruit of this tree, commonly called bay berries, was one of the officinals of the late London Pharmacopoeia, but has been omitted in the British. The tree belongs to Enneasandria Monogynia in the Linnæan system, and to the natural order Lauraceæ. The following is the generic character of Laurus as given by Lindley in his Flora Medica. "Flowers dioecious or hermaphrodite, involucrated. Calyx four-parted; segments equal, deciduous. Fertile stamens twelve in three rows; the outer alternate with the segments of the calyx; all with two glands in the middle or above it. Anthers oblong, two-celled, all looking inwards. Fertile flowers with two to four castrated males surrounding the ovary. Stigma capitate. Fruit succulent, seated in the irregular base of the calyx. Umbela axillary, stalked." Laurus nobilis is an evergreen tree, attaining in its native climate the height of twenty or thirty feet. Its leaves are alternate, on short petioles, oval-lanceolate, entire, sometimes wavy, veined, of a firm texture, smooth, shining, deep-green upon their upper surface, paler beneath. The flowers are dioecious, of a yellowish-white colour, and placed, in small clusters of three or four together, upon a common peduncle in the axis of the leaves. The corolla is divided into four oval segments. The fruit is an oval berry, of the size of a small cherry, and when ripe of a dark-purple, nearly black colour. The bay tree, so famous among the ancients, is a native of the countries bordering on the Mediterranean. Its leaves and fruit, and an oil expressed from the latter, are the parts used.

The leaves have a fragrant odour, especially when bruised, and a bitter, aromatic, somewhat astringent taste. They yield by distillation a greenish-yellow volatile oil, upon which their properties chiefly depend. Water distilled from them has their peculiar odour. The berries when dried are black and wrinkled, and contain two oval fatty seeds, within a thin, friable envelope; or they may be considered as drupes, with a kernel divisible into two lobes. They have the same aromatic odour and taste as the leaves, but are more pungent. Besides an essential oil, they contain also a fixed oil, which may be separated by expression or decoction. The expressed oil, which is obtained from the fresh fruit, is concrete, of a greenish colour, and retains a portion of the volatile oil, which renders it agreeably aromatic. Lard, impregnated with the odorous principle of the berries, and coloured green, is said to be often substituted for the genuine expressed oil. The sophistication may be detected by means of boiling alcohol, which dissolves the laurel oil. The leaves, berries, and oil of the bay tree are excitant and narcotic; but at present are never used internally as
Lawsonia INERMIS. *Henna Plant.* This belongs to Octandria Monogynia in the Linnean system, and to the natural family of Salicarne. It is a shrub growing in the Levant, Egypt, Persia, and India, and well known as the source of a dye-stuff denominated henna, much used throughout the Mahomedan countries of the East. It is largely cultivated in Egypt. The flowers have a strong pungent odour; and a distilled water is prepared from them, used by the women as a cosmetic. The fruit is thought to have emmenagogue properties. But the leaves are the part which constitute the henna of commerce. They are used by the females to give an orange colour to their feet and hands, and a golden hue to their hair. They are also employed to stain common wood in imitation of mahogany. Henna is in the form of powder, which is strongly astringent. It has been chemically examined by Abd-el-Aziz, of Cairo, Egypt, a former pupil in the laboratory for dyeing, connected with the famous manufacture of the Gobelins at Paris. He found in it a brown substance, of a resinoid fracture, having the chemical properties which characterize the tannins, and therefore named it *hennatannic acid.* (Journ. de Pharm., Janv. 1863, p. 35.) Henna is used in medicine, both internally and locally, as a remedy in leprosy and other affections of the skin. The fresh juice of the plant is said by Ainslie to be applied to the same purpose. (Merat et De Lens.)

**LEDUM PALUSTRE.** *Marsh Tea.* Rosmarinus Sylvestris. A small evergreen shrub, growing in swamps and other wet places in the northern parts of Europe, Asia, and America, and in the mountainous regions of more southern latitudes. The leaves have a balsamic odour, and an aromatic, camphorish, bitter taste; and contain, among other ingredients, volatile oil and tannin. They are thought to possess narcotic properties, and have been employed in exanthematic diseases to allay irritation, in hooping-cough, in dysentery, and in various cutaneous affections, particularly leprosy and scabies. In complaints of the skin, they are used both internally and externally in the form of decoction. When placed among clothes, they are said to prevent the attacks of moths. In Germany they are sometimes substituted for hops in the preparation of beer. *Ledum latifolium,* or *Laborador tea,* which is a larger plant than the preceding, is a native of North America, growing in damp places in Canada and the northern parts of the United States. The leaves have an agreeable odour and taste, and are esteemed pectoral and tonic. They are said to have been used as a substitute for tea during the war of independence. (W.)

**LEEK.** *Porrum.* The Bulb of *Allium Porrum.* The leek is a biennial bulbous plant, growing wild in Switzerland, and cultivated in the gardens of Europe and this country for culinary purposes. All parts of it have an offensive pungent odour, and an acrid taste, dependent on an essential oil, which is in a great measure dissipated by decoction, and may be obtained separate by distillation. The bulb, which is the medicinal portion, consists of concentric leaves, like the onion, which it resembles in medical properties, though somewhat milder. It is gently stimulant, with a peculiar direction to the kidneys. The expressed juice may be given in the dose of a fluidrachm, mixed with syrup. This species of *Allium* is not used medicinally in the United States. (W.)

**LEONURUS CARDIACA.** *Common Motherwort.* (Gray's Manual, p. 317.) A perennial labiate herb, thought to be of foreign origin, but growing wild in this country in waste places, around dwellings, &c. The whole plant is used. It has a peculiar aromatic odour and a bitterish somewhat pungent taste, which it no doubt owes to a volatile oil. Its vernacular name implies its possession, in common estimation, of some influence over the uterine functions; and, in the form of infusion or decoction, it is sometimes used in amenorrhoea, suppression of the lochia, and in hysterical affections. (W.)

**LIATRIS SPICATA.** Gay-feather. Button Snakeroot. An indigenous perennial plant, growing in natural meadows and moist grounds throughout the Middle and Southern States. It has a tuberous root, and an erect annual stem, which terminates in a spike of beautiful, purple, compound flowers, appearing in August. The root is said by Schoepf to have a terebinthinate odour, and a warm, bitterish, terebinthinate taste; to be possessed of diuretic properties; and to be useful in gonorrhea and sorethroat; being employed internally in the shape of decoction in the former complaint, and as a gargle in the latter. Pursh informs us that *L. scorosa* and *L. squarrosa* are known in Virginia, Kentucky, and the Carolinas, by the name of *rattlesnake's master;* and that their roots are employed to cure the bite of the rattlesnake, being bruised and applied directly to the wound, while their decoction in milk is taken internally. According to Dr. William P. C. Barton, all the tuberous rooted species of *Liatris* are active plants, and appear to be diuretic. (W.)

**LIGUSTICUM LEVISTICUM.** Lovage. An umbelliferous plant, growing wild in the south of Europe, and cultivated in gardens. The whole plant has a strong, sweetish, aromatic odour, and a warm, pungent taste. When wounded it emits a yellow opaque juice, which concretes into a brownish resinous substance, not unlike opopanax. The roots, stems,
leaves, and seeds have all been employed; but the last have the aromatic properties of the plant in the highest degree. They are small, ovate-oblong, somewhat flattened, curved, strongly ribbed, and of a yellowish-brown colour. The medical properties of lovage are closely analogous to those of angelica. It is a stimulant aromatic, and has been employed as a carminative, diaphoretic, and emmenagogue. The best form for administration is that of infusion. The colouring principle has been isolated by M. J. Nickles, who gives it the name of ligulin, and suggests an important application of it that may be made in testing drinking water. If a drop of its alcoholic or aqueous solution is made to fall into distilled water, it imparts to the liquid its own fine crimson red colour, which undergoes no change; but if limestone water be substituted, the red colour disappears in a few seconds, and is followed by a beautiful blue. (Journ. de Pharm., Mai, 1859, p. 329.)

W.

LIGUSTRUM VULGARE. Privet. A shrub from four to ten feet in height, growing wild both in Europe and the United States, usually in hedges and by the roadside. The leaves, which have an astringent, bitter taste, and the flowers, which are small, snow-white, and of an agreeable odour, have been used in the form of decoction, in sorethroat, and aphthous and scorbutic ulceration of the mouth. The berries are black, have a sweetish, bitter taste, and are said to possess purgative properties, and to colour the urine brown. They are sometimes used for dyeing. The bark was analyzed by M. G. Potex, who found a peculiar substance which he denominated ligustrin, besides mannite, sugar, muco-saccharine matter, starch, chlorophyll, bitter extractive, bitter resin, tannin, albumen, and salts. (Am. Journ. of Pharm., xii. 347.)

W.

LILIUM CANDIDUM. Common White Lily. This well-known plant is a native of Syria and Asia Minor, but has been long cultivated in gardens. The bulb, which consists of imbricated fleshy scales, is without odour, but has a peculiar, disagreeable, somewhat bitter, and mucilaginous taste. It contains much mucilage, and a small proportion of an acrid principle, which is dissipated or destroyed by roasting or boiling. In the recent state, it is said to have been employed with advantage in dropsy. Boiled with water or milk, it forms a good emollient cataplasm, more used in popular than in regular practice. The flowers have an agreeable odour, which they impart to oil or lard; and an ointment or liniment is sometimes prepared from them, and used as a soothing application in external inflammations. A case is recorded by Dr. Jeffries Wyman, of Boston, in which a little girl appeared to have been poisoned by the pollen of the tiger-lily (Lilium bulbiferum), which the child had introduced into her nostrils and probably swallowed. She was affected with vomiting, purging, drowsiness, &c., from which, however, she recovered. (Am. Journ. of Med. Sci., Jan. 1868, p. 271.)

W.

LINT. As an object of great importance to the surgeon, and a necessary article of sale to the apothecary, this seems not only to admit, but to require a brief notice in the present place. The term lint strictly speaking is applicable, as its name implies, to a substance prepared from linen. It is in fact linen made soft and somewhat fleecy by various mechanical processes, so as to render it suitable for the dressing of wounds. The qualities required in good lint are: 1. perfect softness to prevent mechanical irritation to the wound, 2. looseness of texture to render it capable of absorbing the secretions from the surfaces to which it is applied, 3. a certain tenacity so that it may receive unctions dressings, yet with a facility of being torn in one direction, and 4. sufficient firmness of fibre to prevent small portions from being easily separated, and remaining as foreign bodies in the wound. As formerly and still frequently made for domestic purposes, it consists of old linen scraped by means of a knife with the hand, and thus brought into a soft flocculent state, almost destitute of visible fibres. It is obvious that, though this answers some of the above requisitions, it entirely fails to answer others, and is unfit for general surgical use. It will not readily admit of the application of cerates, and must very often leave portions of its substance in the wound, to serve as future sources of irritation. Much better is the old-fashioned lint, made by machines worked by the hand. This was formerly, and may still be made, in large quantities. Old linen was used for the purpose, such as shirts, sheets, tablecloths, &c., and generally in irregular pieces. This was first cleansed thoroughly by washing with soap and water, or by boiling with a weak ley of soda or pearlash. Sometimes, when coloured, it was bleached before being washed. Thus prepared, it was operated on by a simple machine, in which the rag, wrapped round a cylinder, was submitted to the interrupted action of a knife, made to descend upon it at intervals of one-eighth of an inch, so as to cut the thread in one direction. On being removed from the machine, the cut ends of the threads became untwisted and loose, so as to give a flossy character to the fabric. To render it smooth, it was passed through rollers, and its ragged edges were trimmed. Of course it had different degrees of fineness according to the character of the rags used; and this diversity rendered it fit for different purposes; the finer pieces being used merely as a dressing with unctuous matter to exclude the air, while the thicker were better adapted to the absorption of the liquid secretions.

In the progress of improvement, machines were invented and patented for manufacturing
Linum Catharticum.—Liquidambar Styraciflua. PART III.

lint on the large scale. Thus made, it is distinguished in the shops as patent lint. This is generally prepared out of cloth manufactured for the purpose, and therefore has whatever advantage may be derived from uniformity of shape and consistence. In other respects, it is doubtful whether it has any superiority over the old-fashioned article; especially, as, in consequence of competition, cotton, being the cheaper article, has frequently been in part or altogether substituted for linen. It is said that lint may be rapidly prepared, by attaching a piece of linen to the toothed cylinder of the common carding machine. (Med. and Surg. Reporter, Oct. 4, 1862.) Cotton is in several respects inferior to linen for the preparation of lint; and, unless its presence in any manufactured article sold by this name be made known, it should be looked on as a fraudulent substitution. Its fibre is less soft and therefore more likely to irritate; it has much less absorbing power; and it conveys heat less rapidly. The following are methods by which it may be distinguished. (Dr. Eltener.) 1. A linen thread when held erect, and set on fire, appears, after the flame is extinguished, in a smooth continuous form, while cotton thread similarly treated has a tufted aspect. 2. Under a microscope which magnifies 300 diameters, the linen fibre appears to be a straight nearly solid cylinder, with a slender central canal; the cotton, flattened as a piece of tape, with a wide canal, and often twisted like a corkscrew. 3. The potassa test, proposed by Böttger, consists in exposing the doubtful substance to the action of a boiling concentrated solution of potassa. If made of linen, it will in two minutes assume a deep-yellow colour; if of cotton, it will either remain colourless, or will become very faintly yellow; and if the texture be composed of both, it will exhibit a streaked or mottled aspect. The examination must be quickly made, as the yellow colour of the potassa becomes faint with time. 4. Sulphuric acid dissolves the linen fibre, while it leaves that of cotton little changed. 5. Linen thoroughly oiled has the transparent appearance of oiled paper; cotton remains white and opaque. 6. Tinctures of all organic red dye-stuffs, as cochineal, madder, &c., give a much deeper colour to linen than to cotton, and cause a mottled appearance when the two are mixed.

Tow, and hemp in the state of oakum, have been employed for dressing wounds; but they are only applicable as exterior dressings to absorb the pus, when the discharge of this is very copious. Charpie, so much used by French surgeons in dressing wounds from the bottom, generally consists of bundles of straight threads, each four or five inches long, made by unravelling old rather coarse linen. It is much inferior as a dressing for wounds to our best forms of lint. On the subject of lint, we would refer the reader to an article in the Pharmaceutical Journal (x. 241); and to another in the American Journal of Pharmacy (July, 1861, p. 359).

LINUM CATHARTICUM. Purging Flax. This has been brought hither from the first part of the work, because, though formerly one of the Edinburgh officinals, it was discarded in the preparation of the present British standard. The character of the genus to which this plant belongs will be found under Linum, in Part I. Purging flax is an annual plant, six or eight inches high, having erect, slender stems, dichotomous near the summit, furnished with opposite, obvolute-lanceolate, entire leaves, and bearing minute white flowers, the petals of which are obvate and acute. It is a native of Europe, and not found in the United States, where it is never employed as a medicine. The whole plant is very bitter and somewhat acid, and imparts its virtues to water, which acquires a yellow colour. It appears to owe its activity to a peculiar drastic principle, which has received the name of linin, and which is afforded most largely by the plant after the flower has fallen. (Pharm. Central Blatt, 1841, p. 110.) Purging flax formerly enjoyed some reputation in Europe as a gentle cathartic, but fell into disuse. Attention has been again called to it as an excellent remedy in muscular rheumatism, catarrhal affections, and dropsy with disease of the liver. From four to eight grains of the extract, given twice or thrice daily, are said to operate as a purgative and diuretic, without inconvenience to the patient. (Medical Times, July, 1850.) A draught of the powder, or an infusion containing the virtues of two or three draçhms of the herb, may be taken for a dose.

LIQUIDAMBAR STYRACIFLUA. Sweet Gum. An indigenous tree, growing in different parts of the United States from New England to Louisiana, and flourishing also in Mexico, where, as well as in our Southern States, it sometimes attains a great magnitude. In warm latitudes a balsamic juice flows from its trunk when wounded. This has attracted some attention in Europe, where it is known by the name of liquidambar, or copalm balsam, and is sometimes, though erroneously, called liquid storax. It is not afforded by the trees which grow in the Middle Atlantic States, but is obtained in the Western States bordering on the Ohio, and in those further south, as far as Mexico. It is a liquid of the consistency of thin honey, more or less transparent, of a yellowish colour, of a peculiar, agreeable, balsamic odour, and a bitter, warm, and acid taste. By cold it becomes thicker and less transparent. It concretes also by time, assuming a darker colour. It is sometimes collected in the form of tears, produced by the spontaneous concretion of the exuded juice. According to M. Bonastre, it contains a colourless volatile oil, a semi-concrete substance which rises in distillation and is separated from the water by ether, a minute proportion of benzoic acid,
a yellow colouring substance, an oleo-resin, and a peculiar principle, insoluble in water and cold alcohol, for which M. Bonastre proposes the name of styracin. The proportion of benzoic acid is greatly increased by time. Mr. Hodgson obtained from a specimen which he examined 4-2 per cent. (Journ. of the Phil. Coll. of Pharm., vi. 190.) According to Mr. Daniel Hanbury, the acid contained in it is the cinnamic, as is the case in all the products of the liquidambar trees. (Am. Journ. of Pharm., xxix. 478.) Examined by Mr. W. P. Creecy, of Mississippi, it was found, besides a volatile odorous principle, and 30 per cent. of a hard resin, to contain cinnamic acid as the prominent acid ingredient, yet associated with a small proportion of benzoic acid. (Ibid., May, 1860, p. 199.)

Another product is said to be obtained from the same tree by boiling the young branches in water, and skimming off the fluid which rises to the surface. It is of a thicker consistency and darker colour than the preceding, is nearly opaque, and abounds in impurities. This also has been confounded with liquid storax, which it resembles in properties, though derived from a different source. It is said to be used in Texas in coughs. (Gammage, N. O. Med. and Surg. Journ., xii. 696.)

Liquidambar may be employed for the same purpose as storax, but is very seldom used, and is almost unknown in the shops of the United States. The concrete juice is said to be chewed in the Western States in order to sweeten the breath. Dr. Gammage states that the juice is employed popularly in Texas as an addition to excitant ointments. According to C. W. Wright, of Louisville, Ky., the bark of the tree is used with great advantage in the Western States in the diarrhoeas and dysentery of summer, especially in children. It is taken in the form of syrup, which may be prepared from the bark in the same manner as the syrup of wild-cherry bark, according to the U. S. Pharmacopoeia. The dose is a fluidounce for an adult, repeated after each stool. (Am. Journ. of Med. Sci., N. S., xxxii. 129.) The editor of the Va. Medical Journal (Aug. 1856, p. 149) states that the use of a decoction of the bark in milk is common in many parts of Virginia, as a remedy in the diarrhoea of children.

Liquidambar Allingea is said to exude a balsam in the Tenasserim Provinces of India, somewhat resembling liquid storax. (See Pharm. Journ., viii. 243.)

LITHOSPERMUM OFFICINALE. *Gromwell. Milium Solis.* A European perennial, the seeds of which are ovate, of a grayish-white or pearl colour, shining, rather larger than millet seeds, and of a stony hardness, from which the generic name of the plant originated. From an opinion formerly prevalent, that nature indicates remedies adapted to certain diseases by some resemblance between the remedy and the character of the complaint or of the part affected, the seeds of this plant were applied to the treatment of calculous disorders; and they retained their ground in the estimation of physicians as a diuretic, useful in complaints of the urinary passages, long after the fanciful notion in which their use originated had been abandoned. But they are at present considered nearly inert, and are not employed.

LITMUS. *Lacmus. Ed. Tumseol. Tournesol, Orseille, Fr.* This is a peculiar colouring matter derived from Roczella tinctoria and other lichens. Three purple or blue colouring substances are known in commerce, obtained from lichenous plants. They are called severally litmus, orchil, and cudbear. The lichens employed are different species of *Roczella, Leccanora, Varioiaria,* and others. They grow on alpine or maritime rocks, in various parts of the world, and for commercial purposes are collected chiefly upon the European and African coasts, and the neighbouring islands, as the Azores, Madeira, Canaries, and Cape de Verdes. The particular species most employed are probably *Leccanora tartarea or Tarierea moss,* growing in the north of Europe, and *Roczella tinctoria or orchilla weed,* which abounds upon the African and insular coasts, and is called commercially, in common with other species of the same genus, *Angola weed, Canary weed,* &c., according to the place from which it may be brought.

The principles in these plants upon which their valuable properties depend, are themselves colourless, and yield colouring substances by the action of water, air, and ammonia. They are generally acids, and are named lecanoric, orsellin, erythric, &c., according to their use or origin. What is the exact chemical change by which the colouring matters are developed is not determined; but the original body, in some instances at least, undergoes a series of changes, before the ultimate result is obtained. Dr. Stenhouse proposes that the principles should be extracted from the plants at their place of collection, so as to diminish the cost of carriage. For this purpose the lichens, having been finely divided, are to be macerated with milk of lime, the infusion thus obtained to be precipitated with muriatic or acetic acid, and the precipitate to be dried with a gentle heat. Almost the whole of the colouring principles are thus extracted, and obtained in a small bulk. To test the value of the plants as dye-stuffs, they may be macerated in a weak solution of ammonia, or a solution of hypochlorite of lime may be added to their alcoholic tincture. In the former case, a rich violet-red colour is produced; in the latter, a deep blood-red colour instantly appears, but soon fades. All the three colouring substances above referred to may be obtained from the same plant.

*Lacmus* or *litmus* is prepared chiefly if not exclusively in Holland. The process consists
in macerating the coarsely powdered lichens, in wooden vessels under shelter, for several weeks, with occasional agitation, in a mixture of urine, lime, and potash or soda. A fermentation ensues, and the mass, becoming first red and ultimately blue, is after the last change removed, mixed with calcareous or siliceous matter to give it consistency, and with indigo to deepen the colour, and then introduced into small moulds, where it hardens. It comes to us in rectangular cakes, from a quarter of an inch to an inch in length, light, friable, finely granular, of an indigo-blue or deep-violet colour, and scattered over with white saline points. It has the combined colour of indigo and violets, tinges the saliva of a deep-blue, and is somewhat pungent and saline to the taste. From most vegetable blues it differs in not being rendered green by alkalies. It is reddened by acids, and restored to its original blue colour by alkalies.

Its chief use in medicine is as a test of acids and alkalies. For this purpose it is employed either in infusion, or in the form of litmus-paper. The infusion, usually called *tincture of litmus*, may be made in the proportion of one part of litmus to twenty of distilled water, and two parts of alcohol may be added to preserve it. *Litmus-paper* is prepared by first forming a strong clear infusion with one part of litmus to four of water, and dipping slips of white unsized paper into it, or applying it by a brush to one surface only of the paper. The paper should then be carefully dried, and kept in well-stopped vessels, from which the light is excluded. It should have a uniform blue or slightly purple colour, neither very light nor very dark. As a test for alkalies, the paper may be stained with an infusion of litmus previously reddened by an acid.

*Orchil* or archil, as prepared in England, is in the form of a thickish liquid, of a deep reddish-purple colour, but varying in the tint, being in one variety redder than in another. The odour is ammoniacal. It is made by macerating lichens, in a covered wooden vessel, with an ammoniacal liquor, either consisting of stale urine and lime, or prepared by distilling an impure salt of ammonia with lime and water. (*Pereira.*) It is occasionally adulterated with the extracts of coloured woods, as logwood, sappan-wood, &c. A mode of detecting these adulterations is given by Mr. F. Leeshing in the *Chemical Gazette* of June 1, 1855 (p. 219).

*Cudbear* is in the form of a purplish-red powder. It is procured in the same manner as archil; but the mixture, after the development of the colour, is dried and pulverized.

The point in which the preparation of these colouring substances differs from that of litmus appears to be, that potash or soda is added, in the latter, to the ammoniacal liquid used. Orchil and cudbear are employed as dye-stuffs, and sometimes, in like manner with litmus, as a test of acids and alkalies.

**LOLIUM TEMULENTUM.** *Darnel.* *Ivraie.* Fr. One of the Graminaceae or grasses, belonging to the Linnoean class and order Triandra Digynia, indigenous in the old world, but introduced into the U. States, and owing its chief importance to the circumstance that it is apt to grow among wheat and other grains, and thus sophisticate the product with its seeds. From ancient times, these have been supposed to be deleterious to the human system, producing symptoms analogous to intoxication from alcoholic drinks, whence the plant derived its specific name of *Temulentum*, and the French name of *ivraie*. The seeds have a sweetish taste, and are said to contain gluten, starch, and sugar; and there is nothing in their sensible properties which would suggest the idea that they might be poisonous. Indeed, De Candolle states that they are often eaten in bread without inconvenience; and that a beer into which they enter as an ingredient is drank with impunity. (*Mérat et De Lens,* iv. 141.)

The testimony, however, to the fact, that they have a narcotic effect on the system, evincing itself by vertigo, dizziness, headache, sleepiness, and a species of drunkenness, is too strong to be resisted; though very few instances, so far as we know, have been recorded of positively fatal effects from their use. MM. Rivière and Maizière have each recorded a fatal case, which occurred in peasants who had for several days lived upon bread, consisting to the extent of two-thirds or five-sixths of darnel. (*Journ. de Pharm.*, Oct. 1863, p. 280.)

Through thus acting on man, dogs, sheep, and horses, the seeds are said to be wholly innocuous to hogs, cows, and ducks; and poultry have even been fattened by them. The remedy in case of poisoning would be as soon as possible to evacuate the stomach. Lindley states that this is the only one of the grasses which has been satisfactorily proved to have deleterious properties. (*Med. and Economic Bot.*, p. 27.)

**LONICERA CAPRIFOLIUM.** *Honeysuckle.* This ornament of our gardens is a native of the south of Europe. Its sweet-scented flowers are sometimes used in perfumery; and a syrup prepared from them has been given in asthma and other pectoral affections. The expressed juice of the plant has been recommended for the stings of bees, being rubbed directly on the injured spot. The fruit of all the species of Lonicera is said to be emetic and cathartic. (*Mérat et De Lens.*)

**LYCIUM BARBARUM.** *Matrimony Vine.* The genus Lycium belongs to the Linnean class and order Pentandria Monogynia and to the natural order Solanaceae. Different species have been used in various parts of the world in reference to supposed medical virtues. Lycium barbarum, which is indigenous in the south of Europe and in Asia, is a
thorny shrub, with long flexible branches, and is cultivated for hedges and arbours. The leaves and stems were examined chemically by Drs. Housemann and Maree, who succeeded in extracting from them an alkaloid by means of phosphomolybdate of soda. For the mode of proceeding, as well as for the method of preparing the phosphomolybdate used by them, the reader is referred to the American Journal of Pharmacy (May, 1864, p. 226). The alkaloid, which they named lycom (lycom, or more properly, lycoa), is characterized by its strong affinity for water, which causes it to deliquesce in a few minutes after exposure, and renders it very soluble in that liquid. It is also readily soluble in alcohol, but nearly insoluble in ether. It is crystallizable, of a sharp but not bitter taste, and forms crystallizable salts with the acids. The young shoots of one of the species of Lycium are eaten in Spain as asparagus, and its leaves as salad; and the aborigines of New Granada use another species against erysipelas. The leaves of L. barbarum, as well as the fruit, are said to be used by the physicians of Japan. (Mèrat et De Lens.)

LYTHRUM SALICARIA. Loosestrife. Purple Willow-herb. This is an elegant perennial plant, two or three feet high, with an erect, quadrangular, hexagonal, downy, herbaceous stem, bearing opposite, ternate, sessile, lanceolate leaves, cordate at the base, and downy on the under surface and at the margin. The flowers are axillary, forming a leafy verticillate spike. The calyx is red, with unequal segments, the petals purple and undulate, the fruit a small elliptical capsule. The plant grows wild in all parts of Europe, and is found in New England and Canada. It prefers meadows, swamps, and the banks of streams, which it adorns in July and August with its showy purple flowers. The whole herbaceous part is medicinal, and is dried for use. In this state it is inodorous, and has an herbaceous somewhat astringent taste. It renders boiling water very mucilaginous, and its decoction is blackened by the sulphate of iron. Loosestrife is demulcent and astringent, and may be advantageously given in diarrhoea and chronic dysentery, after due preparation by evacuating treatment. It has long been used in Ireland in these complaints, and is said to be a proper remedy in Sweden. The dose of the powdered herb is about a drachm, two or three times a day. A decoction of the root, prepared by boiling an ounce in a pint of water, may be given in the dose of two fluidounces.

MALAMBO or MATIUS BARK. A bark received from South America by Dr. Alex. Ure, under the name of matis bark, was found to have the characters of the malambo bark, which is held in high esteem in New Granada where it is produced, and has been long known to the French pharmacologists. Though conjecturally ascribed by some to a Drimys, and by others to a Croton, its botanical source was unknown till within a few years. It has been ascertained by H. Karston, of Berlin, to be derived from a hitherto undescribed species of Croton, which he names Croton Malambo, and which is described in his recent work entitled “Flora Columbica Terrarumque adventissimae Speciebus Selectis.” This is a small tree or shrub, growing on the coast of Venezuela and New Granada. (Pharm. Journ., Dec. 1859, p. 321.) The bark is described by Dr. Ure as being three or four lines thick, brittle though somewhat fibrous, of a brown colour, and covered with an ash-coloured tuberculous epidermis. It has an aromatic odour, and a bitter pungent taste, and yields these properties to water and alcohol. Its active ingredients appear to be a volatile oil, and a bitter extractive matter. According to Dr. Mackay, it has been used successfully in intermitments, convalescence from continued fever, hemiplegia, dyspepsia, and other cases in which tonic remedies are useful, and also as an adjuvant to diuretics. It is probably nothing more than an aromatic tonic. Dr. Ure has administered it with good effect as a substitute for Peruvian bark. (Pharm. Journ., iii. 160.)

Under the name of Winter’s bark, a considerable quantity of bark was a short time since imported into the United States from South America, which Mr. E. S. Wayne, of Cincinnati, has identified with the malambo bark above described, having found it to correspond with that product both in sensible characters and composition. (Am. Journ. of Pharm., xxix. 1.) We can confirm this decision of Mr. Wayne; as a specimen in our possession answers precisely to the description given by Dr. Ure. The malambo bark, analyzed by Cadet de Gassicourt, yielded volatile oil, bitter resin, and extractive; but no tannic nor gallic acid, and no alkaloid; and the same was the case with the so-called Winter’s bark examined by Mr. Wayne. (Ibid.) The same bark has been analyzed by Mr. F. B. Dancy, who found in it volatile oil, gum, starch, albumen, resin, extractive, fixed oil, wax, and several inorganic substances. (Ibid., p. 219.)

MALVA SYLVESTRIS. Common Mallow. This herb was recognized by the Edinburgh College, but has been discarded by the British Council, and is no longer official. It belongs to the Linnaean class and order Monadelphia Polyandria, and the natural family Malvaceae. The following is its essential generic character. “Calyx double, the exterior three-leaved. Capsules very many, one-seeded.” (Wild.) It is a perennial, herbaceous plant, with a round, hairy, branching, usually erect stem, from one to three feet high, bearing alternate, petiolate, cordate, roughish leaves, which are divided into five or seven crenate lobes, and on the upper part of the stem are almost palmate. The flowers are large, purplish, and placed,
from three to five together, at the axils of the leaves, upon long slender peduncles, which, as well as the petioles, are pubescent. The petals are five, inversely cordate, and three times as long as the calyx. The capsules are disposed compactly in a circular form. This species of mallow is a native of Europe, growing abundantly on waste grounds and by the way-sides, and flowering from May to August. It is sometimes cultivated in our gardens. Other species, indigenous or naturalized in this country, are possessed of the same properties, which are in fact common to the genus. *Malva rotundifolia* is one of the most common, and may be substituted for *M. sylvestris*. The herb and flowers have a weak, herbaceous, slimy taste, without odour. They abound in mucilage, which they readily impart to water; and the solution is precipitated by acetate of lead. The infusion and tincture of the flowers are blue, and serve as a test of acids and alkalies, being reddened by the former, and rendered green by the latter. The roots and seeds also are mucilaginous. Common mallow is emollient and demulcent. The infusion and decoction are sometimes employed in catarrhal, dysenteric, and nephritic complaints; and are applicable to all other cases which call for the use of mucilaginous liquids. They are also used as an emollient injection; and the fresh plant forms a good supplicative or relaxing cataplasm in external inflammation. It was formerly among the culinary herbs.

MANDRAGORA OFFICINALIS. Atropa Mandragora. Linn. Mandrake. Mandragora. A perennial European plant, with spindle-shaped root, which is often forked beneath, and is therefore compared, in shape, to the human figure. In former times this root was supposed to possess magical virtues, and was used as an amulet to promote fecundity, &c.; and the superstition is still cherished by the vulgar in some parts of Europe. The plant is a poisonous narcotic, somewhat similar in its properties to belladonna, to which it is botanically allied. It was much used by the ancients with a view to its narcotic effects; and the root has been recommended by some eminent modern physicians, as an external application to scrofulous, scirrhous, and syphilitic tumours. It is said to have been used by the ancients as an anaesthetic before surgical operations. (Journ. de Pharm., xv. 290.) It is unknown as a remedy in the United States.

MANGANESE. Manganese. This metal and its compounds with oxygen (three regular oxides and two acids) have been already described. (See Manganese Oxiwm Nigrum.) Several of its combinations have been proposed as medicines, and the therapeutic trials, thus far made with them, place them alongside of those of iron as tonic and anti-anemic remedies. It will be recollected that manganese as well as iron is always present, in minute proportion, in healthy blood, and has been detected in various solids and fluids of the body. (See page 530.) According to an analysis by M. Burin-Dubuisson, the amount of manganese in the blood corpuscles is about one-twentieth of that of the iron. It is stated as an advantage of the preparations of manganese, that they may be prescribed in conjunction with tannic acid and the various astringent medicines, which are all incompatible with the preparations of iron. Of the oxides of manganese, the protoxide only is strongly sulphifiable; and this is the oxide present in the ordinary salts of the metal. It may be obtained by precipitation, as a white hydrate, from any of the soluble salts of manganese by the addition of a caustic alkali. This, according to M. Hannon, is a good medicinal preparation; but a strong objection to it is that it rapidly absorbs oxygen, and passes to the state of the brown hydrated sesquioxide. The official deutoxide (native black oxide) is described at page 829, where its medical properties are also noticed. The sulphate of manganese, having been adopted as an official medicine at the late revision of the U. S. Pharmacopoeia, is also described in the first part of this work (page 651). The same is the case with permanganoate or permanganate of potassa, which is fully treated of under the head of Potassum Permanganatum (page 681).

Iodide of Manganese. This iodide may be administered in syrup or pill. Professor Procter has proposed the following formula for the syrup. Dissolve sixteen drachms of sulphate of manganese, and nineteen drachms of iodide of potassium, separately, in three fluidounces of water, each portion of water being previously sweetened with two drachms of syrup. Mix the solutions in a glass-stoppered bottle, and, when the crystals of sulphate of potassa have ceased to precipitate, throw the liquor on a strainer of fine muslin, and allow it to filter into a pint bottle, containing twelve ounces of powdered sugar. When the solution has ceased to wash, pass the filter with a little sweetened water, and add sufficient of that liquid to make the whole measure a pint. Lastly, agitate the liquid until the sugar is dissolved. Prof. Procter states that this syrup contains about a drachm of iodide of manganese in each fluidounce, and corresponds in strength to the official solution of iodide of iron. The small proportion of sulphate of potassa which remains dissolved in the syrup, does not interfere with its medicinal efficacy. The dose is from ten to thirty drops, repeated several times a day. (Am. Journ. of Pharm., Oct. 1860.) M. Hannon makes a pill of iodide of manganese by double decomposition between equal weights of iodide of potassium and crystallized sulphate of manganese. The salts are perfectly dried, accurately mixed in powder, and then rubbed up with honey, so as to reduce the whole to a pillar mass, which may be divided into four grain pills. Assuming that the honey added compensates for the loss of water in drying, each pill will consist of about two grains of iodide of manganese, one of sulphate of potassa,
and one of honey and sulphate of manganese in excess. The dose is one pill daily, gradually increased to six. According to M. Hannon, iodide of manganese is particularly useful in the anemia attendant on scrofula, phthisis, and cancer, and in syphilitic cachexy. Given in conjunction with cinchona, it rapidly removes the enlargement of the spleen often following protracted fevers.

Carbonate of Manganese. This salt may be obtained by the following formula, which is that of M. Hannon, accommodated to the weights and measures of the U. S. Pharmacopoeia. Dissolve seventeen ounces of crystallized sulphate of manganese, and nineteen ounces of carbonate of soda, separately, in two pints of water, a fluidounce of syrup having been previously added to each pint; and, having mixed the solutions in a well-stopped bottle, allow the precipitate to subside. Decant the supernatant liquid, wash the precipitate with sweetened water, allow it to drain from a cloth saturated with syrup, express, mix with ten ounces of honey, and evaporate rapidly to form a pumila mass, which is to be divided into four-grain pills. By a double decomposition between the sulphate of manganese and carbonate of soda, carbonate of manganese is precipitated, and sulphate of soda remains in solution. The sulphate is washed away, and the carbonate is brought to a pumila consistence with honey, which, together with the syrup, prevents the protoxide of manganese in the pill from rising to a higher stage of oxidation. The dose is from two to ten pills daily. Carbonate of manganese was tried by M. Hannon as a medicine on himself. After its use for fifteen days he found his appetite improved, and his pulse increased in force; and he experienced a feeling of sanguineous plethora. He afterwards exhibited the remedy in several anemic cases, with the effect of exciting the functions to a more healthy action, increasing the strength and improving the blood.

Phosphate, tartrate, and malate of manganese have also been proposed by M. Hannon as useful remedies. The phosphate is prepared by double decomposition between sulphate of manganese and phosphate of soda. A syrup of phosphate of manganese has been made by Mr. T. S. Wiegand, of this city. (See his formula in the Am. Journ. of Pharm. for July, 1854.) Dr. Simpson, of Edinburgh, informed one of the authors that a syrup made with two grains of phosphate of iron and one grain of the phosphate of manganese in a fluidrachm of syrup, was much and advantageously used by himself and others in Edinburgh. This may be easily prepared by adding to the two ingredients mentioned five grains of glacial phosphoric acid for each grain of the phosphate of iron. (Pharm. Journ., Nov. 1859, p. 288.) Lactate of manganese has been given, associated with lactate of iron, in chlorosis, in the dose of a grain, increased to five grains.

Ferro-manganic Preparations. M. Hannon conceives that manganese is peculiarly suited to the treatment of anemic cases in which iron has failed, or acts very slowly; but, instead of passing at once from the use of iron to that of manganese, he prefers to give immediately a mixture of the two metals. For this purpose he recommends the following formula. Take of crystallized sulphate of iron six drachms and a half; crystallized sulphate of manganese two drachms; carbonate of soda nine drachms; honey five drachms. Rub together, and with syrup make a mass, to be divided into four-grain pills. In this pill both the metals are present as carbonates; and, as the sulphate of soda is not washed away, it contains that salt also. The dose is from two to six pills daily. (See the paper of M. Hannon, Journ. de Pharm. 3e ser., xvi. 41 and 189; also a note of the favourable results obtained by M. Pétrequin, of Lyons. Ibid., xvi. 381.) Further experience has confirmed the favourable opinion of M. Pétrequin in relation to the therapeutic value of the ferro-manganic preparations. A number of formulas have been devised by M. Burin-Dubuisson, of Lyons, for making them, containing the metals variously combined; but the most important of them is the syrup of iodide of iron and manganese, for the preparation of which we prefer the following formula by Prof. Procter. Take of iodide of potassium 1000 grains; sulphate of protoxide of iron 630; sulphate of protoxide of manganese 210; iron filings 100; sugar, in coarse powder, 4800. Powder the iodide and sulphates separately, and, having mixed them with the filings, add half a fluidounce of distilled water, and triturate to a uniform paste. Then add another half fluidounce of distilled water to the paste, and triturate again; and, after an interval of fifteen minutes, add a third half fluidounce, and mix. Next transfer the magma of salts to a moistened filter, supported on a funnel, and allow them to drain into a bottle, holding a little more than twelve fluidounces, and containing the sugar. After they have drained, add cold boiled water by small portions at a time, until the solution of the iodides has been displaced and washed from the crystalline magma of sulphate of potassa. Finally, add sufficient cold boiled water to make the whole measure twelve fluidounces. The object of the iron is to prevent the liberation of iodide. This syrup has a very pale straw colour. It contains a little sulphate of potassa, which does not injure it as a therapeutic agent. If the salts have not been all decomposed during their reaction, it will be greenish. Each fluidounce contains 50 grains of the mixed iodides, in the proportion of 3 parts of iodide of iron to 1 of iodide of manganese. The dose is from ten drops to half a fluidrachm. (Am. Journ. of Pharm., May, 1863, p. 198.) Syrup of iodide of iron and manganese is considered by M. Pétrequin to be particularly suited to the treat-
ment of anaemia, resulting from obstinate intermittent fevers, prolonged suppuration, and scleroulous, syphilitic, and cancerous affections.

Dr. T. S. Speer, of Cheltenham, in imitation of the practice of M. Hannon and M. Pétrequin, has employed the combined carbonates of iron and manganese with excellent effects; but, instead of using the carbonate in pill, protected by honey and syrup, as M. Hannon has done, he prefers a saccharine carbonate of the two metals, in imitation of the London saccharine carbonate of iron, made by the following formula. Dissolve three ounces and one drachm of sulphate of iron, one ounce and one scruple of sulphate of manganese, and five ounces of carbonate of soda, each, in thirty Imperial fluidounces of water, and thoroughly mix the solutions. Collect the precipitated carbonates on a cloth filter, and wash them immediately with cold water, to separate the sulphate of soda. Then press out as much water as possible, and, without delay, triturate the pulp with two and a half ounces of finely powdered sugar. Lastly, dry the mixture at a temperature not exceeding 120°. The saccharine carbonate of iron and manganese, as thus prepared, is a reddish-brown powder, devoid of all taste, except that imparted by the sugar. The dose is five grains, gradually increased to a scruple, three times a day, given with the meals, or immediately after them. (See Ana. Journ. of Pharm., March, 1864, p. 127, from Med. Times and Gaz.)

B. MEAT BISCUIT. This alimentary substance, containing much nutriment in a small bulk, is the invention of Mr. Gail Bordon, jun., of Texas. It is made by mixing a concentrated fluid extract of flesh, strained through wire-cloth, and freed from fat, with good wheat flour, or other meal, and baking two parts of the extract into a biscuit, which must be preserved, in mass or coarse powder, free from moisture, in gutta percha bags, or air-tight casks or cases. To make the dough, about two parts of the extract are mixed with three of the flour; and about 20 per cent. is lost in baking. The extract contains the soluble ingredients of the flesh, not congelable by heat; namely, gelatin, kreatin, kreatinin, the phosphoric, lactic, and inosinic acids, and certain salts. Of course it contains no albumen nor fibrin, unless in some altered state in which they are rendered soluble at a boiling temperature. In this nutritious biscuit, the absence of albumen and fibrin is supposed to be supplied by the gluten of the flour. To prepare a pint of palatable soup, an ounce of the powdered biscuit, first made into a thin paste with cold water, is added, with constant stirring, to sufficient boiling water, and the whole boiled for twenty minutes. Salt and pepper are then added to suit the taste. The meat biscuit forms an important resource in all cases in which food must be carried on long journeys for daily consumption.

Preserved meat-juice is a nutritive liquid, prepared by Mr. Gillon, a manufacturer of preserved meats, at Leith, in Scotland. The process for making it, as described by Prof. Christison, is as follows. A number of cylindrical cases of tinned iron, each containing six pounds and a half of beef, and closed by soldering with a lid, having a hole half an inch wide in the middle of it, are placed in an iron cylinder, surrounded with an iron jacket so as to leave an interstice, and heated by steam, admitted into the interstice, to the temperature of 220° for about three hours. The cases are then withdrawn, and the juice is poured out, amounting to a few ounces for each case, and, after cooling, is entirely freed from fat. It is next poured into four-ounce tin cases, which are closed as before, with a small aperture in the lid secured with solder. These are subjected to a temperature of 220° in a chlorid of calcium bath for some time, and, when removed from the bath, are opened by melting the solder which secures the aperture; whereupon steam rushes out, and carries with it the air which may have collected in the upper part of the case. As soon as the gaseous matter ceases to be expelled, the aperture is resoldered. The process of heating in the bath, tapping, and resoldering is then repeated; and the cases are finally painted, to preserve them from rust. Dr. Christison states that he has repeatedly opened cases, eighteen mouths in his possession, and found the contents to possess the rich delicate aroma and taste of fresh beef-juice. Mr. Gillon's meat-juice contains only 6-5 per cent. of solids, consisting of osmazome, with the salts, and sapid and odorous principles of meat. It contains neither fibrin, albumen, nor gelatin. It may be taken in the concentrated form, but is generally best diluted. The contents of a case (four ounces) will make sixteen ounces of strong beef tea, by the addition of the requisite quantity of boiling water. (See Med. Exam., March, 1855.)

Pemmican is an alimentary substance, containing much nutriment in a small bulk, which is used by fur-traders and others, as their exclusive food, on long journeys in the north-west of this continent. It is made, according to Dr. C. C. Keeney, U. S. Army, by mixing equal weights of buffalo meat and buffaloo tallow. The meat, thoroughly dried in the sun, is reduced to powder, and the tallow in the melted state is added to it, and the whole well stirred. The melted mixture is then poured into sacks of untanned buffalo hide, capable of containing from twenty to forty pounds. No salt is used, and yet the mixture keeps perfectly well. (Med. Statistics, U. S. Army, p. 68.)

B. MEDEOLA VIRGINICA. Gyrornia Virginica. Nuttall. Indian Cucumber. An indigenous perennial herb, growing in all parts of the United States. The root, which in shape and flavour bears a strong resemblance to a small cucumber, is said by Pusch to be eaten by
the Indians. According to the late Professor Barton, it has been thought useful in diseases, and probably possesses diuretic properties. It is figured and described by Dr. William P. C. Barton in his Medical Botany.

**MELILOTUS OFFICINALS.** **Melilot.** An annual or biennial plant, indigenous in Europe, and growing also in this country. We have two varieties, one with yellow, the other with white flowers, which are considered by some as distinct species. The plant, when in flower, has a peculiar sweet odour, which, by drying, becomes stronger and more agreeable, somewhat like that of the tonka bean. Indeed, according to M. Guilleminette, the odorous principle of the two substances is identical. (Journ. de Pharm., xx. 172.) The taste of melilot is slightly bitter. It has little medicinal power, and, though formerly recommended in various diseases, is at present not employed internally. As a local application, it is used in decoction or cataplasm, in moderate inflammations, though probably with little other advantage than such as results from the combination of warmth and moisture.

**MENISPERMUM CANADENSE.** **Mooneed. Yellow Parilla.** This is a climbing plant, growing in various parts of the United States, from the northern boundary to the Gulf of Mexico. It is described in the Flora of North America by Torrey and Gray (i. 48), and in Gray's Manual of the Botany of the U. States (p. 18). The root or rhizomes is long, of a yellow colour, and a bitter taste. Considerable quantities of a root were some time since brought to the market of Philadelphia from New Orleans, and offered for sale as Texas sarsaparilla. This was satisfactorily shown by Prof. Robert F. Thomas to be the root of Menispermum Canadense. (Am. Journ. of Pharm., xxvii. 7.) In an unpublished inaugural dissertation by Dr. Geo. F. Terrell (Feb. 1844), it is stated that the root of this plant is considerably employed in Virginia, both in domestic practice and by physicians, as a substitute for sarsaparilla, in scrofulous affections. It has a bitter taste, and is said to be a gently stimulating tonic. Its natural affinity with the columbo plant, both belonging to the family of Menispermaceae, and the sensible properties of its root, naturally suggested that this might contain the same or similar active principles with columbo; and Mr. Maisch, in a recent examination, has determined that among its constituents are bornein in small proportion, and a white or colourless alkaloid in larger quantity, which has an alkaline reaction on litmus and turmeric paper, is precipitated by tannin, phosphomolybdic acid, and iodohydrargyrate of potassium, and is soluble in ether, alcohol, and a large proportion of water. (Am. Journ. of Pharm., July, 1863, p. 302.)

**MENYANTHES TRIFOLIATA.** **Buckbean. Marsh Trefoil.** The leaves of this plant were recognised in the late Edinburgh Pharmacopoeia, but, having been omitted in the British, are noticed in this place, in accordance with our plan of introducing into the third part of the work all the medicines which have ceased to be officinal. Menyanthes trifoliata belongs to the Linnaean class and order Gentianacea, with the following generic character. "Corolla biaurata. Stigma bifid. Capsule one-celled." (Wild.) The plant has a perennial, long, round, shghted, horizontal branching, dark-coloured root, or rhizome, with the entire surface of the finger, and sending out numerous fibres of the same kind. The leaves are ternate, and upon long stalks, which proceed from the end of the root, and are furnished at their base with sheathing stipules. The leaflets are ob ovate, obtuse, or bluntly denticulate, very smooth, beautifully green on their upper surface, and paler beneath. The flower-stalk is erect, round, smooth, from six to twelve inches high, longer than the leaves, and terminated by a conical raceme of whitish, somewhat rose-coloured flowers. The calyx is five-parted; the corolla funnel-shaped, with a short tube, and a five-cleft, revolute border, covered on the upper side with numerous long, fleshy fibres. The anthers are red and sagittate; the germ ovate, supporting a slender style longer than the stamens, and terminating in a bifid stigma. The fruit is an ovate, two-valved, one-celled capsule, containing numerous seeds. This beautiful plant is a native both of Europe and North America, growing in boggy and marshy places, always moist, and occasionally overflowed with water. It prevails, in the United States, from the northern boundary to Virginia. In this country the flowers appear in May, in England not till June or July. All parts of it are efficacious, but the leaves only are officinal.

The taste of buckbean is intensely bitter and somewhat nauseous, the odour of the leaves faint and disagreeable. Its virtues depend on a bitter principle, denominated menyanthin, which may be obtained sufficiently pure for use by treating the spirituous extract of the plant with hydrated oxide of lead, removing the lead by hydrosulphuric acid, filtering and evaporating the liquor, exhausting the residue with alcohol, and again evaporating with a gentle heat. It has a pure bitter taste, is soluble in alcohol and water, but not in pure water, and is chemically neuter. (Pharm. Cent. Blatt, A.D. 1843, p. 24.)

**Medical Properties and Uses.** With the ordinary properties of the bitter tonics, menyanthes unites a cathartic power, and in large doses is apt to vomit. It was formerly held in high esteem in Europe as a remedy in numerous complaints, among which were intermittent, rheumatism, scrofula, scurvy, dropsy, jaundice, and various cachectic and cutaneous affections. In most of these it was administered under a vague impression of its alternative
powers. It is little employed in this country; but, as it is a native plant, and applicable to cases where a combined tonic and purgative effect is demanded, it is desirable that country practitioners should be aware of its properties. The dose of the powdered leaves or root as a tonic is from twenty to thirty grains; of an infusion, prepared with half an ounce to a pint of boiling water, from one to two fluidounces; and of the extract ten or fifteen grains, to be repeated three or four times a day. A drachm of the powder, or a gill of the strong decoction generally purges, and often occasions vomiting.

MERCURIALIS ANNUA. An herbaceous European plant, of the family of Euphorbiaceæ, which has been employed, from the most ancient times, as a purgative and emmenagogue. It has also been considered by some as diuretic, and has been used in the treatment of syphilitic affections. When boiled, it loses its acrid properties, and in this condition has been used as an emollient. Another species, M. perennis, also a native of Europe, is ranked among poisonous plants. (Mérot et De Lens.) But what has recently recalled attention to the annual species is the discovery in it, by Reichardt, of a new volatile alkaloid, which he proposes to name mercurialin ('mercurialia'). This is a liquid, of an oily appearance, narcotic odour, and alkaline reaction; boils at 284° F.; forms salts with the acids; absorbs carbonic acid; has a strong affinity for water; on exposure to the air is changed into a resin of a buttery consistence; and is very poisonous in its action on man. For the mode of procuring it, see Annaire de Thérapeutique (1864, p. 44). The existence of a volatile alkaloid in the Mercurialis, suggests that other Euphorbiaceæ may owe their acrid properties to a similar constituent.

MESEMBRYANTHEMUM CRYSTALLINUM. Ice-plant. A biennial plant, growing spontaneously in the south of Europe, and cultivated as a curiosity in colder countries, by the aid of artificial warmth. The stem and under surface of the leaves are covered with crystalline drops, which give the plant the appearance of being coated with ice. The herb is without smell, and has a saline somewhat nauseous taste. It is considered demulcent and diuretic, and has been commended as a remedy in various complaints, especially those of the mucous membrane of the lungs and urinary passages. It has also been used in dropsy. The expressed juice is the form in which it has been generally employed.

MSENNA. Museenna. Bienna. Under these different names has been brought into notice, as a powerful vermifuge, the bark of an Abyssinian tree, the botanical character of which has recently been determined by M. Brongniart from dried specimens brought to Paris by M. Courbon. The tree is leguminous, and belongs to the family of the Mimoææ. M. Brongniart names it Albizzia anthelmintica. The bark is in flat pieces from five to ten inches long, smooth, slightly fissured, of a rusty-gray colour exteriorly, and pale-yellow and fibrous within. It consists of four layers, one of which contains very large cells, with thick coats, and is supposed to be the active part. MM. E. Caveutou and Legendre have examined the bark, and found in it no alkaloid, but a peculiar, acid, resinous substance, having an acrid taste, analogous to that of the bark, of which it is probably the active principle. The Abyssinians employ the powdered bark, in the dose of about two ounces, which they take in various ways, suspended in water or other liquid, or mixed with flour in the form of bread, or made into a confection with honey, butter, &c. It is taken in the morning, three or four hours before breakfast, and no other precautions are used. It produces no pain nor any disturbance of the functions, not even purging actively. Fragments of the worm are voided the same evening, and the greater portion of it the next day. Successful trials of the remedy have been made elsewhere than in Abyssinia, though M. Raye has collected cases which tend to discontinue the opinion of its vermifuge powers. But the bark may in these instances have been injured by time. (See Ann. de Théâp., 1862, p. 101.)

MESQUITE GUM. Gum Mesquite. Gum Mesquita. This is the product of Algarobia glandulosa (Torrey and Gray, Flœr of N. Amer., i. 393), a small thorny tree or shrub, belonging to the family of Mimoææ, and growing in New Mexico, Texas, and other neighbouring regions, where it covers vast extents of country. Captain R. B. Marcy, of the U. S. Army, who commanded an expedition sent by our government into that region, gives a particular account of the tree, in a letter to Messrs. Rushton & Co., of New York. He states that it was first described by Dr. Edwin James, who attended Colonel Long's exploring expedition to the Rocky Mountains upwards of forty years since. The specimens collected by Dr. James were submitted to Dr. Torrey, by whom the botanical character of the plant was determined. According to Captain Marcy, the tree is found between 26° and 36° of N. latitude, and extends from 97° to 103° of longitude, over a region containing more than 500,000 square miles. In its botanical affinities and habits, it is closely analogous to the Acacia, which yield gum arabic. The fruit is a long, compressed pod, filled with a sweet pulp, which is said to be used as food. A gum exudes from the stem and branches, especially when wounded, which hardens in the dry season, sometimes in masses as large as a hen's egg.

Specimens of this gum were collected, and sent for examination to various persons in the Atlantic cities, by Dr. Geo. G. Shumard, of the U. S. Army, who was attached to Captain Marcy's expedition. A portion received by one of the authors was in irregular, ornish
pieces, of various sizes, and of different hues, from colourless transparency to a dark amber-brown. Some of them had the fissured appearance of the best Turkey gum. Examined by Professor Procter, the gum was found to resemble gum arabic in its solubilities, but to differ from it essentially in some of its chemical reactions. The most striking points of difference are that solution of gum mesquite is not precipitated by subacetate of lead, and a strong solution is not coagulated by borax. (Am. Journ. of Pharm., xxvii. 224.) Dr. Campbell Morat, of Baltimore, found it to approximate very closely to gum arabic in ultimate composition, its constituents being carbon, hydrogen, and oxygen, with three per cent. of inorganic matter. He found also a very little bassorin (0·026 per cent.), which did not exist in the specimens examined by Prof. Procter. (Am. Journ. of Sci. and Arts, March, 1855, p. 264.) There can be little doubt that this gum has all the valuable medicinal properties of gum arabic, and might be substituted for it in all cases, with this considerable advantage, that it may be added to diluted solution of subacetate of lead, so as to communicate to that preparation demulcent properties, in addition to those of a sedative and astringent, for which it is so much used as a local application.

MITCHELLA REPENS. (Gray's Manual, p. 172.) *Partridge-berry. Checker-berry. Winter Clover.* This must not be confounded, in consequence of its common name, with Gautheria procumbens. It is a small, evergreen, trailing indigenous plant, creeping about the roots of trees, with fragrant flowers, and a berry-like, edible fruit, of a scarlet colour, which lasts through the winter. The whole plant is supposed to possess remedial properties, and is said to be employed, in decoction, by the Indian squaws to facilitate parturition. It appears to be diuretic, tonic, and astringent, resembling in these respects the pipsissewa, and may be used for the same purposes, and in the same manner as that plant.

MOMORDICA BALSAMINA. *Baltsam Apple. Balsamina.* An annual climbing plant, a native of the East Indies, but cultivated in our gardens for the sake of the fruit. This is ovate, attenuated towards each extremity, angular, warty, not unlike a cucumber in appearance, of a lively red or orange-yellow colour, easily falling when touched, and spontaneously separating into several pieces. It was formerly highly esteemed as a vulnerary, and is still in use among the common people. A liniment formed by infusing the fruit, deprived of its seeds, in olive or almond oil, is applied to chapped hands, burns, old sores, piles, prolapsus ani, &c.; and the fruit itself is sometimes mashed, and used in the form of poultice. According to M. Descourtilz, it is poisonous when taken internally, having proved fatal to a dog in the quantity of two or three drachms. An extract prepared from it is said to be useful in dropy, in the dose of from six to fifteen grains.

MONESIA. Under this name, a vegetable extract from South America was, a few years since, introduced to the notice of the medical profession in France by M. Bernard Derosne, and for a time attracted much attention. Its origin was for some time uncertain; but at present it is believed to be derived from the bark of *Chrysophyllum glycyphleum,* a tree of middling size, growing in the forests near Rio Janeiro, and elsewhere in Brazil. (Journ. de Pharm., 3e sér., vi. 63.) Specimens of the bark were obtained along with the extract.

The bark is in pieces, some of which are three or four lines thick, is very compact and heavy, of a deep brown or chocolate colour, contrasting strongly with the grayish colour of the epidermis when this remains, and of smooth fracture. The extract was received from S. America in cakes weighing rather more than a pound, from three-quarters of an inch to an inch in thickness, of a dark-brown almost black colour, very brittle, of a fracture neither very dull nor very shining, and of a taste at first sweet, then astringent, and ultimately acid; the acrimony being very persistent, and especially felt in the fauces. It is entirely soluble in water. The bark was analyzed by MM. Derosne, Henry, and Payen, and found to contain, in 100 parts, 1·2 of stearin, chlorophyll, and wax, 1·4 of glycerichin, 4·7 of an acid principle analogous to saponin, called monesin, 7·5 of tannic acid, 9·2 of a red colouring substance, 1·3 of malic acid and malate of lime, 3·0 of various salts, including silica and oxides of iron and manganese, and 71·7 of pectic acid or pectin and of lignin, including loss, besides traces of an aromatic principle and of gum. Monesin was obtained by treating the bark or extract with alcohol, adding to the tincture an excess of hydrate of lime in fine powder, filtering, evaporating the clear liquor to dryness, treating the residue with water and animal charcoal, filtering, and again evaporating to dryness. Thus procured it was in transparent yellowish scales, which were easily pulverized, forming a white powder. It was uncrystallizable, readily soluble in alcohol and water, to the latter of which it gave the property of frothing, and insoluble in ether. It had no power to saturate acids, was without odour, but had a slightly bitterish taste, followed by a decided and permanent acrimony in the posterior mouth and fauces. (Jour. de Pharm., Janvier, 1841.) Monesia owes its activity probably to this principle and to tannic acid.

The effects of this medicine upon the system appear to be those of a moderate stomache excitant, a general alterative, and a feeble astringent. In overdoses it is said to produce heat in the epigastrum, with obstinate constipation and tenesmus. It has been used internally with asserted advantage in diarrhoea, haemoptysis, menstraghia, scrofula, sourvy, the
chronic catarrh of old people, and dyspepsia. As a local remedy it has been found useful in leucorrhœa, ulcerations of the mouth and fauces, spongy and scorbutic gums, carious teeth, and obstinate scrofulous and otherwise unhealthy ulcers upon the surface. The extract may be given in pill or powder, in aqueous solution, in tincture, or in syrup. The dose of it is from two to ten grains, repeated every hour, two, or three hours, or less frequently. From ten grains to a drachm may be given daily. In scrofulous affections, it must be given in large quantities, and persevered in for several weeks, in order to obtain its curative effects. Monesia is applied to ulcers either by being sprinkled in powder upon the surface, or in the form of ointment made with one part of the extract and seven parts of simple ointment. Mosenin, or the acrid principle, has been given internally in the dose of about half a grain, and has also been applied to ulcers.

Mr. Dupuy, of New York, states that specimens of an extract sold as monesia, which have come under his notice, bear so close a resemblance to extract of logwood as to suggest the inquiry, whether they might not really have been the product of the same plant. (N. Y. Journ. of Pharm., i. 167.)

MOXA. The term moza is employed to designate small masses of combustible matter, intended, by being burnt in contact with the skin, to produce an eschar. They are of various forms, and made of different materials. The Chinese moza is in small cones from eight to twelve lines in height, and is prepared from the leaves of one or more species of Artemisia. 'A. Chinentia and A. Indica' were indicated by the Dublin College; but Lindley states that it is the A. Moza of De Candolle which is employed. According to some authors, the part used is the down which covers the leaves and stems; but others, with greater probability, assert that it is a fine lanuginous substance, prepared from the leaves by beating them in a mortar. A coarser and a finer product are obtained, the former of which is used for tinder, the latter worked up into moza. A similar moza has been made in France, by a similar process, from the leaves of A. vulgaria.

Various substitutes have been proposed for the Chinese moza, all composed of some light, porous, soft, inflammable substance, which burns slowly, and thus allows the heat to be regulated according to the effect desired. Linen rolled into a cylinder, cotton formed into the same shape and enclosed in a piece of linen, cords of cotton in small masses of various shapes, and even common spunk made from the agaric of the oak, have been employed by different persons with the desired effect. But all these bodies are subject to the inconvenience of requiring to be constantly blown upon, in order that their combustion may be sustained. To remedy this defect, cotton impregnated with nitre has been recommended; and the moza usually employed is prepared from that substance. It is important that the impregnation should be uniform; as otherwise different parts of the cylinder, burning with different degrees of rapidity, would produce unequal effects upon the skin. The following process is recommended. One pound of cotton is introduced into a vessel containing two ounces of nitre dissolved in half a gallon of water, and a moderate heat applied till all the liquid is evaporated. The cotton when perfectly dry is formed into thin, narrow sheets, which are rolled round a central cord of linen, so as to form a cylinder from half an inch to an inch in diameter, and several inches long. This is enclosed in a covering of silk or linen sewed firmly around it: and, when used, may be cut by a razor into transverse slices a few lines in thickness. By leaving a hole in the centre of the cylinder, the combustion will be rendered more vigorous, and a deeper eschar produced.

The pith of Helianthus annuus, or the common sun-flower, has been proposed by M. Percy for the preparation of moza, for which it is well adapted by the nitre which it contains, and which enables it to burn without insufflation. The stem, when perfectly mature, is cut into transverse sections about half an inch in thickness, which must be carefully dried, and kept in a perfectly dry place. They have this advantage, that, in consequence of the retention of the cortical portion, they may be held with impunity, while burning, between the fingers of the operator. They are, however, often defective in consequence of an insufficient of nitre in the pith, or of the unequal inflammability of different parts.

M. Robinet has perfected the preparation of moza, by combining the advantages of the two kinds last described. He rolls cotton round a small central cylinder of pith, and envelopes the whole in a piece of muslin, which is more or less firmly applied, according to the degree of compactness required. The cylinders, thus made, burn without assistance, uniformly, and with a rapidity proportionate to their firmness.

Dr. Jacobson, of Copenhagen, has proposed, as a substitute for the ordinary forms of moza, small cylinders formed out of strips of paper imbued with a solution of chlorate of potassa; and cotton, impregnated with the solution of chlorate of potassa instead of nitre, is said to answer an excellent purpose. (Journ. de Pharm., xix. 608.) Small cylinders made out of strips of coarse muslin saturated with the same solution are also employed. M. Guerpratt proposes paper or cotton dipped into the solution of subacetate of lead, and afterwards dried. (Med. Exam., N. S., iii. 455.)

Lime in the act of slaking has been employed by Dr. Osborne. A portion of quicklime, half an inch in thickness, and of suitable lateral dimensions, is applied to the
skin, and confined by some convenient arrangement. A few drops of water are then added, and a degree of heat is soon evolved sufficient for a caustic effect, if the lime is allowed to remain as long as the heat continues. This may be increased or diminished by increasing or diminishing the quantity of lime employed. The eschar formed is somewhat more than double the extent of the base of the moxa. (Dublin Journ., Jan. 1842.)

Medical Uses. Cauterization by fire, in the treatment of disease, has been commonly practised among savage and half civilized nations from the earliest periods of history, and has not been unknown as a remedy in the most polished communities. The ancient Egyptians and Greeks were acquainted with the use of moxa; and in China, Japan, and other countries of Asia, it appears to have been employed from time immemorial. From these countries the early Portuguese navigators introduced it into Europe; and the term moxa is said to have been derived from their language, though supposed by some to be of Chinese origin. The true Chinese name is said to be kiee. (Peray and Laurent.) Some years since, the remedy became very popular in France, and attracted some attention in this country. It acts on the principle of revulsion; relieving deep-seated inflammation, and local irritation whether vascular or nervous, by inviting the current of excitement to the skin. In some cases it may also operate advantageously by the propagation of a stimulant impression to neighbouring parts.

The celebrated Larrey was among those who contributed most to bring this remedy into repute. The diseases in which it was recommended by this author were anaurosis, loss of taste, deafness, paralytic affections of the muscular system, asthma, chronic catarrh and pleurisy, phthisis, chronic engorgement of the liver and spleen, rachitis, diseased spine, coxalgia, and other forms of scrofulous and rheumatic inflammation of the joints. It has also been used advantageously in neuralgia, and is applicable to chronic complaints generally in which powerful external revulsion is indicated.

The parts of the body upon which, according to Larrey, it should not be applied, are the cranium where protected only by the skin and pericranium; the eyelids, nose, and ears; the skin over the larynx, trachea, and mammary glands; over superficial tendons, projecting points of bones, and articular prominences in which the capsular ligament might be involved; the anterior surface of the abdomen; and the genitals.

As a general rule it should be applied as near as possible to the seat of the disease; and, in neuralgic or paralytic cases, at the origin or over the course of the nerves proceeding to the part affected. Some advise that the cylinder be attached to the skin by some adhesive liquid; but a more general practice is to retain it in the proper position by a pair of forceps or other instrument. Larrey recommends that the skin around it be covered with a piece of moistened lint, having a hole in the centre to admit the base of the cylinder. The moxa should be set on fire at the summit, and the combustion sustained if necessary by the breath, the blow-pipe, or the bellows. The size of the cylinder should vary, according to the effect desired, from half an inch to an inch or more in diameter, and from a few lines to an inch in height. Any degree of effect may be obtained, from a slight inflammation to the death of the skin, by regulating the time during which the moxa is allowed to burn. When a slough is required, it should be suffered to burn until consumed. The first sensation experienced is not disagreeable; but the operation becomes gradually more painful, and towards the close is for a short time very severe.

MUREXIDE. A fine purple dye-stuff, made by the reaction of nitric acid on uric acid. As resulting from the action of nitric acid on urine, it was supposed by Mr. Prout to consist of purpuric acid and ammonia, and hence was named purpurate of ammonium; but chemists are not agreed as to its precise composition. It is now made from guano. This is first treated with muriatic acid to remove foreign substances, and then with soda to dissolve the uric acid, which is separated by neutralizing the soda with muriatic acid. The uric acid is dissolved in nitric acid, the solution is heated, and after it cools ammonia or its carbonate is added, which develops the purple colour. Murexide is obtained in crystals, which have a square form, and are of a rich green colour by reflected, but of a purplish by transmitted light. They are slightly soluble in cold water, more so in boiling water, and insoluble in alcohol and ether. With potassa they form a rich purple solution. (Brande and Taylor.) See for an article on the subject of murexide the Pharmaceutical Journal (xviii. 328).

MURIATIC ETHER. Ether Muriaticus. Muriate of Ethyle. Chloride of Ethyl. This ether was discovered by Rouelle, but first obtained in sufficient quantities to permit the examination of its properties by Basse. It may be procured by several processes, but the following is the best. Distil a mixture of equal measures of concentrated muriatic acid and alcohol, and receive the product, by means of a curved glass tube, in a tubulated bottle, half filled with water at a temperature between 70° and 80°, and connected by means of a second tube with another bottle, loosely corked, and surrounded by a mixture of common salt with snow or pounded ice. The ether, as it enters the first bottle, is mixed with alcohol and acid, which are retained by the water; while the pure ether passes forward, and is condensed in.
the refrigerated bottle. It must be kept in strong bottles, well secured with ground stoppers covered with leather. Before being opened, the bottle should be cooled to the freezing point.

Muriatic ether is a colourless liquid, having a strong, slightly saccharine, allaceous taste, and a penetrating, ethereal, allaceous smell. Its sp. gr. at the temperature of 41° is 0.774. It is extremely volatile, entering into ebullition at 64°; so that in summer it may be collected in the gaseous state, in bell-glasses over water. Its density in the state of vapour is 2.22. When kindled as issuing from a fine orifice, it burns with an emerald-green flame without smoke, diffusing a strong odour of muriatic acid; but, when set on fire in quantities, it burns with a greenish-yellow, smoky flame. Water dissolves one-fiftieth of its weight of this ether, and acquires a sweetish, ethereal taste; and alcohol unites with it in all proportions. These solutions are not precipitated by nitrate of silver, showing that the chlorine present is in a peculiar state of combination. Like hydric and nitric ether, it dissolves sulphur and phosphorus, the fat and volatile oils, and many other substances. It consists of one eq. of muriatic acid 36.6, and one of ethylen 28 = 64.6; or, in volumes, of two volumes of the acid, and one volume of the vapour of ethylen, condensed into two volumes. Its formula is \(\text{C}_2\text{H}_4\text{HCl}\). Viewed as the chloride of ethyl, it is represented by \(\text{C}_2\text{H}_6\text{Cl}\).

Muriatic ether is a diffusible stimulant; but, owing to its extreme volatility, cannot be kept in the shops. It may, however, be preserved in a cool cellar, the temperature of which does not rise above 45° or 50°, being well secured in bottles, which should be placed reversed. When used as a medicine, it is generally mixed with an equal bulk of alcohol, forming what is called alcoholic muriatic ether. The dose is from five to thirty drops, given in sweetened water, or other convenient vehicle.

B. MUSHROOMS. Fungi. This extensive family of cryptogamous plants is interesting to the physician, from the consideration, that, while some of them are very largely consumed as food, others are deleterious in their nature, and capable, when eaten, of producing poisonous effects. Their substance is made up of a cellular tissue, which is usually of that soft consistence denominated fungous, but is sometimes corky, ligneous, or even gelatinous. Many of them have an agreeable odour and taste, while others are unpleasant or offensive both to the nostrils and palate. Their juice generally exhibits an acid reaction. According to Braconnot, most of them contain, among other substances, a peculiar principle denominated fungin, a peculiar acid called fungic acid usually combined with potassa, and a saccharine matter, less sweet than most other varieties of sugar, less soluble in alcohol and water than that of the cane, and distinguished by some writers as the sugar of mushrooms. M. Bolby found mannite in two different species, with ozalic acid in one, an acid which he supposed to be the fumaric in a second, and lichesteareic acid in a third. (Journ. de Pharm., 3e sér., xxiv. 236.) M. Dessaignes has ascertained the identity of the fumaric and fungic acids. (Ibid., xxvi. 133.) Fungin constitutes the basis of these vegetables, and is the principle upon which their nutritive properties chiefly depend. It is the fleshy substance which remains after they have been treated with boiling water holding a little alkali in solution. It is whitish, soft, and insipid; inflammable; insoluble in water, alcohol, ether, weak sulphuric acid, and weak solutions of potassa and soda; soluble in heated muriatic acid; decomposed by nitric acid, and by concentratred alkaline solutions; and converted by destructive distillation into substances resembling those which result from the distillation of animal matters. MM. Payen and Fromberg affirm that the fungin of Braconnot is nothing but cellulose; and this assertion is confirmed by M. Gobley, who attributes the animal properties ascribed to it, to the presence of unseparated albumen. M. Gobley also found the supposed peculiar saccharine matter to be mannite. He gives, as the result of his analysis of the edible mushroom, water, albumen, cellulose, mannite, extractive matters, salts, and fatty matter consisting of olein, margarin, and a peculiar concrete fatty substance analogous to cholesterin, and called by him agaracin. (Ibid., xxix. 91.) Mushrooms are very largely cultivated in Europe for the table. They require a rich soil; but the discovery is asserted to have been recently made, that they will flourish better, and attain a much greater size, in artificial beds of sulphate of lime, in which the spores are buried mixed with powdered nitrate of potassa to the depth of about one-third or one-half of an inch; at least this is said to be true of a variety of the Agaricus campesiens, called by the French "l'agaric de couche." (Journ. de Pharm., Sept. 1861, p. 196.) It is highly important for those who employ mushrooms as food, to be able to distinguish those which are wholesome from the poisonous. The following general rules are given by M. Richard in the Dictionnaire des Droguers. Those should be rejected which have a narcotic or fetid odour, or an acrid, bitter, or very acid taste; which occasion a sense of constriction in the throat when swallowed; which are very soft, liquefying, changing colour, and assuming a bluish tint upon being bruised; which exude a milky, acid, and styptic juice; which grow in very moist places, and upon putrefying substances; in fine, all such as have a corrosive, ligneous, or corky consistence. The last, however, are injurious in consequence rather of their indigestible than of their poisonous nature. Even mushrooms which are usually edible may prove poisonous, if collected too late, or in places which are too moist. It is said, moreover, that the poisonous species sometimes become innocent
Mushrooms.—Musk, Artificial.

PART III.

when they grow under favourable circumstances. It is affirmed, for example, that mush-
rooms which prove poisonous in England are eaten with impunity in Russia, a fact which
Mr. W. Hamilton is disposed to ascribe less to difference in the plant, than in the mode of
preparation. No doubt, more large potatoes used with them by the Russian than the Eng-
lish cooks. (Pharm. Journ. ii. 67.) In the autumn of 1859, out of six officers of the French
army stationed at Corte, who partook of mushrooms, five died. In consequence of this
event, the Army Board of Health drew up instructions for the use of the army as to the
mode of distinguishing the poisonous from edible mushrooms. We have no space for them
here; and must content ourselves with referring to the Journal de Pharmacie (Nov. 1860, p.
339); and the Pharmacetical Journal (Jan. 1861, p. 287). Immense quantities of mushrooms
are eaten in France, Germany, Italy, and other parts of continental Europe; and they are
said to constitute the chief food of the people in certain provinces.

Some experiments of M. Gerard would tend to show that poisonous mushrooms may be
rendered innocent, by treating them with water slightly acidulated with vinegar, before
cooking them. About a pound avoidispois of poisonous mushrooms, cut into pieces, are
to be macerated for two hours in a quart of water, acidulated with two or three spoonfuls
of strong vinegar, and afterwards to be washed with a large quantity of water. Next day
they are to be put into cold water, boiled for half an hour, then taken out, washed, and
dried. They are now fit for food. (See Am Journ. of Pharm., xxv. 274.) But subsequent
experiments by MM. Demartis and Corne, of Bordeaux, have proved that this method is
not always to be relied on; as certain mushrooms, after having been treated in the manner
suggested, have nevertheless produced fatal effects on animals; and, as the same mush-
rooms may be poisonous at one season or in one situation, and innocent in another, the
inference is that those experimented on by M. Gerard, though ordinarily poisonous, may
not have been so in that particular instance. (Journ. de Pharm., 3e sér., xxi. 468.)

The symptoms produced by the poisonous mushrooms are anxiety, vertigo, nausea, faint-
ness, vomiting, and, if they are not rejected from the stomach, somnolence, stupor, small
and intermittent pulse, tension of the abdomen, cold extremities, livid skin, and death in
thirty-six or forty-eight hours. Sometimes violent pains in the stomach and bowels are
experienced; and occasionally severe vomiting and purging occur, and save the patient.
Blackish or bloody dejections, with tenesmus, sometimes attend the action of the poison.
The symptoms are not generally experienced until some hours after the mushrooms have
been eaten, showing that their deleterious effects depend upon the entrance of the poisonous
principle into the circulation. The remedies are emetics, if the physician is called in time,
accompanied with the free use of warm drinks, and followed by cathartics. After the
evacuation of the alimentary canal, demulcent and nutritive beverages should be given,
and the strength of the patient sustained by mild tonics or stimulants. Ether is particu-
larly recommended; and opiates would no doubt prove serviceable in the absence of coma,
should any irritability of the stomach and bowels remain.

Some of the poisonous species have been used as medicines; but in this country they are
never employed; and too little seems to be precisely known of their modes of action,
and their qualities, even in the same species, vary too much, according to the circum-
stances of their growth and situation, to justify their introduction into the materia medica,
without further investigation. A species of Lycoperdon or puff-ball, L. proteus, was thought
to have been proved by Dr. B. W. Richardson, of London, to have remarkable narcotic
and anaesthetic properties. Having noticed that the smoke of this fungus was used in the
country for stupefying bees, he experimented with the fumes upon various animals, which,
when caused to inhale them, became insensible, and could be operated on without evincing
any signs of pain. When carried far, they caused death. He had himself inhaled the
fumes clarified by passing them through water, and experienced symptoms of intoxication
and drowsiness. They were procured by burning the fungus. (Lond. Med. Times and Gaz.
June, 1853, p. 610.) Mr. Thornton Herapath, however, maintains, as the result of his ex-
periments, that these anaesthetic effects are in reality not owing to any narcotic principle
present in the fungus, but to the carbonic oxide gas generated during their combustion.
(Philosoph. Magaz., July, 1855.)

W. MUSK, ARTIFICIAL. Moschus Fastiatius. This is prepared, according to M. Elsner, by
adding, by small portions at a time, one part of rectified oil of amber to three parts of fum-
ing nitric acid. The resulting resin is washed with water to separate acid, and brought to
the consistency of a firm extract in a water-bath. Thus prepared it is a dark brownish-red
substance, emitting a pungent aroma, and, a mucky odour. It is very soluble
in alcohol, ether, and the volatile oils; and its alcoholic solution reddens litmus. Triturated
with caustic potassa, it gives off ammonia. When set on fire, it burns with a very smoky
flame, and leaves a shining porous charcoal. Its formula, deduced from its combination with
prortoxide of lead, is C₄H₂N₂O₇. Comparing its composition with that of the oil of amber,
the action of the nitric acid evidently consists in eliminating a portion of carbon and hydro-
gen, adding to the oxygen, and furnishing nitrogen. M. Elsner found oil of amber to con-
sist of several oil principles, having different boiling points, one of which, resembling
cupion, he calls amber cupion. As this substance yields artificial musk by the action of fuming nitric acid, he believes the property possessed by oil of amber yielding the same substance to be due to its presence. (Journ. de Pharm., 8e sér., ii. 144.) During the reaction of nitric acid with oil of amber, Dr. John T. Plummer, of Indiana, has observed that oxalic acid is generated.

Dr. S. W. Williams gives the following formula for the preparation of artificial musk. Add gradually, drop by drop, three drachms and a half of concentrated nitric acid to a drachm of rectified oil of amber, contained in a glass tumbler or very large wineglass. The mixture grows hot, and emits offensive fumes, which the operator must avoid. When the ordinary nitric acid is employed, which is not of full strength, the reaction must be assisted by heat; in which case Dr. Williams recommends that the vessel containing the mixed ingredients be placed in a plate before the fire, they being, meanwhile, continually stirred with a glass rod. After the mixture has remained at rest for 24 hours, it acquires a resinous appearance, and divides into two portions, an acid liquid below, and a yellow resin above, resembling musk in smell. This being thoroughly washed, first with cold and then with hot water, until all traces of acid are removed, is the artificial musk. (See Am. Journ. of Pharm., viii. 14.)

Artificial musk is an antispasmodic and nervine, and possesses the general therapeutic properties of the natural substance, though in a weaker degree. It is praised by Dr. Williams in the treatment of hooping-cough, typhoid states of fever, and nervous diseases generally. When combined with water of ammonia, compound spirit of lavender, or laudanum, he found no remedy so efficient in the sinking faintness occurring in the last stage of pulmonary consumption. The average dose for an adult is ten grains; for a child of two years old, from half a grain to a grain, repeated, in each case, every two or three hours. It may be prepared as the musk mixture, or with almonds in the form of emulsion. According to Berzelius, tincture of artificial musk is formed by dissolving a drachm of the musk in an ounce of alcohol, equivalent to ten fluidrachms, of the sp. gr. 0.935. Of this the dose for an adult is a teaspoonful. This tincture has been employed by Prof. Hauner, chief physician of the Children's Hospital at Munich, in uncomplicated spasm of the glottis, with invariable success in more than thirty cases. Though artificial musk is not equal in power to the natural substance, when genuine, yet it is in all probability superior to the adulterated article, so frequently sold under the name of musk.

MYRICA CERIFERA. Wax-myrtle. Bay-berry. This is an indigenous shrub, growing in great abundance in the sandy soil along the sea-shore, and even on the shores of our northern lakes. It belongs to Dictis Tetrandria in the Linnean system, and the natural order Myricaceae. The genus is characterized by its sterile flowers in cylindrical, and its fertile in ovoidal closely imbricated catkins, without calyx or corolla, solitary under a scale-like bract with a pair of bractlets; the stamens 2 to 8, with filaments somewhat united below; the ovary with 3 scales at its base, and 2 thread-like stigmas; the fruit a small spherical nut. (Gray's Manual.) The leaves of the wax-myrtle are oblong-lanceolate, narrower at their base, entire or somewhat toothed near the apex, shining, with resinous dots on both sides, and very fragrant when rubbed. The fruit is covered with a coating of white wax, and sometimes continues on the plant for two years or more. The shrub is from three or four to ten feet high, often thickly crowded, and, under such circumstances, scenting the air with its spicy odour. The coating of wax upon the surface is collected, and known in commerce as myrtle wax. (See Vegetable Wax, page 241.) A volatile oil might probably be collected by distillation from the leaves, and used for purposes similar to those to which oil of pimento is applied. The bark of the stem and root is supposed to possess valuable remedial properties, and has been employed to a considerable extent. In the dried state it is in quilled pieces of variable length, covered with a thin epidermis of a greyish colour somewhat mottled, and marked with slight circular fissures. Within the epidermis the colour is reddish-brown. The bark is brittle, and of a peculiar, astringent, bitterish, and pungent taste, followed by a slight sense of acrimony. Its powder has a peculiar aromatic odour, and irritates the nostrils and throat when inhaled. It yields its virtues to water and alcohol. Chemically examined by Mr. Geo. M. Hambright, it was found to contain volatile oil, starch, lignin, gum, albumen, extractive, a red colouring substance, tannic and gallic acids, an acid resin soluble in alcohol and ether, an astringent resin soluble in alcohol and not in ether, and a peculiar acrid principle having acid properties, analogous to saponin, for which the name of myricinic acid is proposed. (Am. Journ. of Pharm., May, 1865, p. 193.)

In relation to its effects on the system, the bark appears to be moderately tonic and astringent, with probably expectorant properties connected with its acrid principle, and in large doses emetic. It has been considerably used by the "eclectics," in diarrhoea, jaundice, scrofula, &c. Externally the powdered bark is used as a stimulant to indolent ulcers; and the decoction as a gargle and injection in chronic inflammation of the throat, leucorrhoea, &c. The dose of the powder is twenty or thirty grains, of a decoction made with an ounce of water, one or two fluidounces. An alcoholic extract, very inappropriately named myrrhin, is given in the medium dose of about five grains.
MYROBALANS. *Myrobalani.* These are the fruits of various East India trees, particularly of different species of *Terminalia.* They are noticed here partly on account of their ancient reputation, partly because they are still occasionally to be found in the shops, though seldom if ever used in medicine. Five varieties are distinguished by authors. 1. *Myrobalani bellirici.* These are obtained from *Terminalia Bellirica.* They are roundish or ovate, from the size of a hazelnut to that of a walnut, of a grayish-brown colour, smooth, marked with five longitudinal ribs, and sometimes furnished with a short, thick footstalk. They consist of an exterior, firm, resinous, brown, fleshy portion, and an interior kernel, which is light-brown, inodorous, and of a bitterish very astringent taste. 2. *Myrobalani chebulic.* This variety is produced by *Terminalia Chebula.* The fruit is oblong, pointed at each extremity, from fifteen to eighteen lines in length, of a dark-brown colour, smooth and shining, with five longitudinal wrinkles, but without footstalks. In their internal arrangement and their taste, they resemble the preceding. 3. *Myrobalani citrinus vel flavus.* These are from a variety of the same tree which affords the last-mentioned myrobalans, from which they differ only in being somewhat smaller, of a light-brown or yellowish colour, and of a taste rather more bitter. They were formerly sometimes sold in the shops of Philadelphia, under the name of *white galls,* to which, however, they bear no other resemblance than in taste. 4. *Myrobalani Indicus vel nigric.* These are thought to be the unripe fruit of *Terminalia Chebula,* or *T. Bellirica.* They are ovate-oblong, from four to eight lines long, and from two to three lines thick, of a blackish colour, wrinkled longitudinally, and presenting, when broken, a thick brown mass, without kernel, but with a small cavity in the centre. They are sourish and very astringent. 5. *Myrobalani emblica.* This variety is wholly different from the preceding, and derived from a plant having no affinity to the *Terminalia,* namely, the *Phyllanthus Emblica,* of Linnaeus. It is often in segments, as kept in the shops. When the fruit is entire, it is blackish, spherical, depressed, of the size of a cherry, presenting six obtuse ribs with as many deep furrows, and separating into six valves, and has a strongly astringent and acidulous taste. These fruits were in high repute with the Arabs, and were long employed by European practitioners, as primarily laxative and secondarily astringent, in various complaints, particularly diarrhoea and dysentery. Their dose was from two drachms to an ounce. They are not now employed as medicines. We have been told that they have been used as a substitute for galls in the preparation of ink-powder.

NAPTHALIN. This may be obtained by subjecting coal tar to distillation, when it passes over after the coal naphtha. It is a white, shining, crystalline substance, fusible at 176° and boiling at 423°. According to Kopp, its sp. gr. in the liquid state is 0:9774, according to Alluard, at 210° F., 0:9628. (Journ. de Pharm., Avril, 1869, p. 318.) It is soluble in alcohol, ether, naphtha, and the oils, but insoluble in water. Notice has already been taken of the artificial preparation of alizarin, a colouring principle of madder, from naphthalin, by M. Roussin. (See Rubia, page 716.) It has been proposed by Dupasquier as an expectorant, and has been found, on trial, to act decidedly as such. In the impending suffocation, sometimes occurring in the chronic pulmonary catarrh of old persons, and in humoral asthma, it facilitated expectoration in a remarkable degree. Being a stimulating remedy, it is not proper in acute bronchitis, or where pulmonary inflammation exists. The dose is from eight to thirty grains, given in emulsion or syrup, and repeated at intervals of a quarter of an hour, until an abundant expectoration takes place. (Journ. de Pharm., 3e sér., ii. 513.) M. Rossignon considers naphthalin to act like camphor, and to be capable of replacing it on many occasions as a remedy. It produces excellent effects in verminous affections. It has been found useful by M. Emery, in the form of ointment, made by mixing a scruple of naphthalin with five drachms of lard, in dry tetter, psoriasis, and lepra vulgaris. (Annuaire de Thérap., 1843, pp. 64 and 66.)

NAPLES YELLOW. A yellow pigment prepared by calcining a mixture of lead, sulphuret of antimony, dried alum, and muriate of ammonia, or a mixture of carbonates of lead, diaphoretic antimony, dried alum, and muriate of ammonia. (Gray.)

NARCISSUS PSEUDO-NARCISSUS. *Daffodil.* This well-known bulbous plant is a native of Europe, but very common in the gardens of this country, where it attracts attention by the early appearance of its conspicuous yellow flowers. Both the bulb and flowers have been used in medicine. The latter have a feeble peculiar odour, and both have a bitter mucilaginous taste. They are emetic, though uncertain in their operation. It is probable that the flowers of the wild plant are more powerful than those of the cultivated. They may be given dried and powdered, or in the form of extract. The dose of the powder, to produce an emetic effect, varies, according to the statements of different physicians, from a scruple to two scruples; while the extract is said to vomit in the dose of two or three grains. It is conjectured that the emetic property is developed by the agency of water. The bulb is most powerful in the recent state, and, within our own knowledge, is occasionally used as an emetic in domestic practice in the country. When dried and powdered, it has been given in the dose of thirty-six grains without vomiting. The author, when a
Nard.—Nitrate of Copper.

PART III.

student of medicine, wishing to ascertain whether this root might not, like \textit{specunamin}, possess diaphoretic properties, took a dose of it suspended in some warm water at bedtime, and on awaking in the morning found himself bathed in a copious sweat, and freed, at the same time, from the symptoms of a severe attack of catarrh under which he was at the time labouring. The flowers are said also to possess antispasmodic powers, and have been used in France, with supposed advantage, in hooping-cough, epilepsy, and other convulsive affections. It is probable, however, that they operated in these cases by their nauseating or emetic property. They have, moreover, been advantageously employed in diarrhoea, dysentery, and intermittent fever. Other species of \textit{Narcissus} are said to possess the same properties, though they have not been so much used.

W. NARD. Spikenard. Several aromatic roots were known to the ancients under the name of \textit{nardus}, distinguished, according to their origin or place of growth, by the names of \textit{nardus indica}, \textit{nardus Celtica}, \textit{nardus montana}, &c. They are supposed to have been derived from different species of \textit{Valeriana}. Thus the \textit{nardus Indica} is referred to \textit{V. Jatamensi} of Bengal, the \textit{nardus Celtica} to \textit{V. Celtica}, inhabiting the Alps, Apennines, &c., and the \textit{nardus montana} to \textit{V. tuberosa}, which grows in the mountains of the south of Europe. The Indian nard, or spikenard, sometimes also called Syrian nard, is still occasionally to be found in the shops. It is a small delicate root, from one to three inches long, beset with a tuft of soft, light-brown, slender fibres, of an agreeable odour, and a bitter, aromatic taste. It was formerly very highly esteemed as a medicine, but is now almost out of use. Its properties are analogous to those of the officinal valerian.

W. NASTURTIUM OFFICINALE. R. Brown. \textit{Sisymbrium Nasturtium}. \textit{Linn. Water-cress}. A small, perennial, herbaceous, succulent plant, growing in springs, rivulets, and ponds, in North America, Europe, and some parts of Asia. The fresh herb has a quick penetrating odour, especially when rubbed, and a bitterish, pungent taste, but loses both when dried. In sensible and medical properties it bears some resemblance to scurry grass, though milder, and on this account is preferred for the table. It is thought to be useful in scorbutive affections, and visceral obstructions. The expressed juice is sometimes given in the dose of one or two ounces; but the herb is more frequently used in the form of a salat. Other species of Nasturtium, as \textit{N. Palustre} or marsh water-cress, and \textit{N. amphibium} or water-raddish, grow in similar situations with the \textit{N. officinale}, and possess similar virtues.

W. NERIUM OLEANDER. A notice of the oleander, so well known as an ornamental shrub of our conservatories, is introduced here mainly on account of its presumed poisonous properties. The peasantry in the south of France, where the plant grows wild, employ the powdered bark as a poison for rats, and death is said to have occurred from eating food roasted by the oleander wood. (\textit{Méret et De Lens}.) The leaves, boiled in lard or oil, yield an ointment which is said to be very efficacious, rubbed on the skin, against insects that infest the person. A case has been recently recorded in which a man, in Hindostan, swallowed somewhat more than an ounce of the juice of \textit{Nerium odorum}, with the effect of producing the most violent narcotic symptoms, as stupor, stertorous breathing, and convulsions, followed by great prostration, with involuntary evacuations, from which, however, after two days of danger, he recovered under the use of emetics, followed by supporting treatment. (\textit{B. and F. Med.-Chir. Rev.}, Am. ed., April, 1860, p. 387.) M. Latour has made a careful chemical examination of oleander, from which he obtained the following results. 1. The poisonous principle exists in the leaves, bark, and flowers, but most largely in the bark. 2. This principle is of a resinous nature, and not volatile, and is found more largely in the wild than the cultivated plant. 3. The solubility of this resin in water is much facilitated by the alkaline salts, and hence it exists in the watery extract. 4. The distilled water of the bark and leaves possesses some activity, which it owes to a small portion of the resin carried over with the steam. (See \textit{Am. Journ. of Pharm.}, March, 1856, p. 172.)

W. NIGELLA SATIVA. Nutmeg-flower. Small Fennel-flower. A small annual plant, growing wild in Syria and the south of Europe, and cultivated in various parts of the world. The seeds, which are sometimes kept in the shops under the name of \textit{semen nigellae}, are ovate, somewhat compressed, about a line long and half as broad, usually three-cornered, with two sides flat and one convex, black or brown externally, white and oleaginous within, of a strong, agreeable, aromatic odour, like that of nutmegs, and a spicy, pungent taste. Their chief constituents are a volatile and fixed oil, and a peculiar bitter principle denominated \textit{nigellin}, which exists in the seeds in very minute proportion. (\textit{Journ. de Pharm.}, 9e sér., XI. 128.) In India they are considered as stimulant, diaphoretic, and emmenagogue, and are believed to increase the secretion of milk. They are also used as a condiment and as a corrigent or adjuvant of purgative and tonic medicines.

W. NITRATE OF COPPER. \textit{Cuprum Nitratus}. This well-known salt has been employed with advantage, as a caustic, in a severe case of ulceration of the throat and tongue, and in several similar cases, by Dr. William Moore, of Ballymoney, Ireland. The application is attended with no danger, provided the ulcer or part is dried before applying the caustic, and afterwards smeared with oil. (\textit{See Braithwaite's Retrospect}, xiv. 201.)
NITRATE OF SODA. Cubic Nitre. This salt may be formed by treating carbonate of soda with nitric acid. It is found naturally in the desert of Atacama and elsewhere in Peru, where it forms beds of vast extent. Attempts were made between 1820 and 1830 to export it to England and the United States; but the cargoes were unsalable. Soon afterwards, however, its value became known; so that at present large quantities are exported from Peru, being consumed in the manufacture of sulphuric and nitric acids, and as a fertilizer. The salt has also been found largely in Brazil, in the Province of Bahia, near the river San Francisco. (Am. Journ. of Pharm., Nov. 1861, p. 502. For a particular account of the nitrate of soda deposits of Peru, in a commercial point of view, see Ibid., March, 1862, p. 263.)

The crude salt, as it comes from Peru, is in saline lumps, rather soft and friable, and damp on the surface. It is distinguished into varieties according to its colour and state of aggregation, as white compact, yellow, gray compact, gray crystalline, and white crystalline, and varies very much in purity, containing from 55 to only 20 per cent. of the pure salt. Some of the varieties contain iodine. (See page 47.) The impurities consist of common salt, sulphate and carbonate of soda, and chloride of calcium. Occasionally boreate of lime, associated with boreate of soda, is found under the beds of the nitrate. (See page 754.)

Nitrate of soda, when pure, is a white salt, crystallizing in rhomboidal prisms, and having a sharp, cooling, and bitter taste. It attracts moisture slightly from the air, and dissolves in about twice its weight of water, at 60°. It has been praised as a remedy in dysentery by two German physicians, Drs. Velsen and Meyer, given in the quantity of from half an ounce to an ounce in the course of the day, dissolved in gum water, or other mucilaginous liquid. It has been used with success in the same disease by Dr. Rademacher, of Vienna, who recommends it in a number of other diseases having nothing in common (Ann. de Thérap., 1854.) Dr. J. B. Brown also bears very emphatic testimony to the value of nitrate of soda as a speedy and safe remedy in dysentery and dysenteric diarrhoea. (Charleston Med. Journ., May, 1854, p. 398, from North-Western Med. and Surg. Journ.)

As nitrate of soda has been imposed upon our merchants for nitre, it may be useful to mention that the former salt may be distinguished by its giving rise to an orange-yellow flame when thrown on burning coals, and by the rhomboidal shape of its crystals; those of nitre being long six-sided prisms.

NITROPRUSSIDE OF SODIUM. This is the most interesting of a series of salts, discovered by Dr. Playfair, called nitroprussides, which are produced, for the most part, by saturating nitroprussic acid, formed by the action of nitric acid on ferrocyanide of potassium, with different bases. The sodium salt is best obtained by the process of A. Overbeck, as follows. Dissolve four parts of powdered ferrocyanide of potassium, contained in a flask, in five and a half parts of commercial nitric acid, diluted with an equal weight of water. After the action is completed, which generally occupies about ten minutes, and is accompanied by a copious evolution of gases, heat the resulting coffee-brown liquid in a water-bath, until a drop of it gives a dingy green, instead of a blue precipitate, with a solution of sulphate of protoxide of iron. Then allow the liquid to cool; whereupon the larger part of the nitrate of potassa generated will be deposited in crystals. Pour off the green mother-liquor from these, and separate the remaining nitrate of potassa by repeated concentrations. Next neutralize the liquid, while heated in a water-bath, with carbonate of soda, taking care to add the carbonate so long only as a pure blue precipitate is produced. Lastly, filter the solution, and set it aside for the formation of crystals, which must be washed with water, and dried between blotting-paper. (Chem. Gaz., July 15, 1853, p. 271.) This salt is in the form of large, ruby-coloured, prismatic crystals, very much resembling those of ferricyanide of potassium (red prussiate of potassa). It is soluble in two and a half parts of cold water, and in a less quantity of hot water. Its solution, exposed to sunshine, is decomposed, with evolution of nitric oxide gas, and deposition of Prussian blue, at the same time acquiring a green colour. Nitroprusside of sodium, as well as the other soluble nitroprussides, is the most delicate test for the alkaline sulphures, with which it strikes a beautiful violet colour. Its composition is not certainly known; but the following formula, given by Gerhardt, is probably the correct one: Na₂Fe₆(CN)₅NO₂+4H₂O. Nitroprussic acid is the nitroprusside of hydrogen, with the formula H₂Fe₆(CN)₅NO₂.

NITROSULPHATE OF AMMONIA. This compound, discovered by Pelouze in 1835, may be formed by passing nitric oxide through a solution of sulphate of ammonia in five or six times its volume of water of ammonia. A large number of crystals are formed, which must be quickly washed with water of ammonia previously refrigerated, and dried without heat. Nitrosulphate of ammonia has been used at the Hôtel-Dieu in Paris, in cases of twelve grains, with apparent advantage, in typhoid fever. Its composition corresponds with one eq. of nitric oxide, one of sulphurous acid, and one of ammonia; but as the salt is not precipitated by baryta water, Pelouze conceives that the nitric oxide and sulphurous acid, together, form a peculiar acid which he calls nitro sulphuric acid, consisting of one eq. of nitrogen, one of sulphur, and four of oxygen (NSO).
NITROUS OXIDE. This gas, well known from its power to cause a transient intoxication when breathed, is capable of producing anesthetic effects; but, even if these were as safely induced as by ether, the comparative expense of the gas would be an objection to its employment. The late Mr. Horace Wells, dentist, of Connecticut, tried to introduce it as an anesthetic; but his first experiments were unsuccessful, and further attempts were superseded by the discovery of etherization. Recently, however, it is said to have been used to a considerable extent by the dentists, and with satisfactory results. It is alleged in its favour, that its operation, while equally effectual, is more pleasant and transitory than that of ether or chloroform, and that no serious consequences have been experienced. (Bost. Med. and Surg. Jour., Oct. 15, 1863, p. 226.) As a remedial agent it is probably capable of beneficial application in cases requiring the use of a powerful nervous and cerebral stimulant; and some trials have been made with it in low forms of fever, in which it appeared to act favourably.

Water, impregnated by pressure with about five times its volume of this gas, forms the nitrous oxide water, known in England under the name of Searle's patent oxygenous aerated water, which has been used to some extent as an internal remedy. Sir H. Davy tried the aqueous solution, made without pressure, and thought it acted as a diuretic, and promoted digestion; and Sçullas used it in Asiatic cholera with apparent advantage. The patent water is assorted to be suited to the treatment of torpor, debility, depression of spirits, asthma, and dyspepsia; but to be contraindicated in inflammatory and other states of the system. Dr. George Ziegler, of Philadelphia, has made a number of therapeutic trials with nitrous oxide water, charged with five times its volume of the gas, and finds it to possess tonic, resolvent, exhilarant, and diuretic properties. He has observed, however, that its free and prolonged use is apt to produce emaciation. Dr. Ziegler has also made some interesting experiments, tending to show the antidotal and reviving properties of nitrous oxide. In these experiments, dogs were asphyxiated or poisoned with carburetted hydrogen, chloroform, carbonic acid, hydrocyanic acid, and other agents, and, when in a state of suspended animation more or less complete, were generally revived by the nitrous oxide water, injected into the bowels in the quantity of from two to three pints. When administered by the stomach, the dose of the water is from half a pint to a pint and a half, taken in the course of the day. Dr. Ziegler concludes from his observations and experiments that nitrous oxide is a powerful arterial, nervous, and cerebral stimulant, possessing, at the same time, valuable antidotal powers. (Bost. Med. and Surg. Journ., xlvi. 463 and xlvii. 383.)*

NYMPHEA ODORATA. Sweet-scented Water-lily. An indigenous herbaceous perennial, growing in most parts of the United States, in fresh water ponds and on the borders of streams, and distinguished by the beauty and delicious odour of its large, white, many-petaled flowers. Its root is large and fleshy in the recent state, but becomes light, spongy, and friable by drying. It is very astringent and bitter, and, according to Dr Bigelow, contains much tannin and gallic acid. It is sometimes employed, in the form of poultice, as a discutient application. The root of the Nymphæa alba, or European white water-lily, was esteemed antiphlogisic by the ancients, but has long lost this reputation. Like that of the American plant, it is bitter and styptic, and may have been used by its asstringency in some cases of leucorrhœa, gonorrhœa, dysentery, &c., in which it was formerly employed for its reputed sedative virtues.

OCHRES. These are native mixtures of argillaceous or calcareous earth and oxide of iron, employed in painting. They are prepared for use by agitating them with water, decanting the turbid liquor after the coarser particles have subsided, then allowing it to rest in order that the finer parts may be deposited, and, lastly, drying the sediment which forms. The colour of the ochres varies with the state of oxidation of the iron, and with the proportion which it bears to the other ingredients, and is sometimes artificially modified by the agency of heat. Several varieties are kept in our shops under different names, according to their colour or place of origin. Such are the brown ochre, the yellow ochre, the red ochre, the Roman ochre of a brownish-yellow changing by heat to a purple-red, the Oxford ochre of a brownish-yellow colour less deep than the Roman, and the French ochre which is yellow. The Indian red from the Persian Gulf, and the Spanish brown may also be ranked in this class of pigments. Sometimes ochres come in a powdery state, and sometimes in hard masses; in the latter state they are called stone ochres.

OCYUM BASILICUM. Basil. An annual plant, a native of India and Persia, and cultivated in Europe and in this country in gardens. The whole plant has a strong, peculiar, agreeable, aromatic odour, which is improved by drying. The taste is aromatic, and somewhat cooling and saline. It yields by distillation a yellowish-green volatile oil, lighter than water, which on being kept solidifies into a crystalline camphor, isomeric if not identical with turpentine-camphor. (Gmelin's Handbook, xiv. 359.) Basil has the ordinary pro-

---

* In a letter addressed to one of the authors by Mr. R. C. Clark, it is stated that the writer had been effectually cured of severe neuralgia by taking a fluid ounce of the nitrous oxide water every six hours.
PART III. Enanthe Crocata.—Oil of Anda.

Properties of the aromatic plants, and is in some places considerably used as a condiment. The seeds are said by Ainslie to be used in India, in the form of infusion, as a remedy in gonorrhea and nephritic affections.

GENANTHE CROCATA. Hemlock Water-dropwort. A perennial, umbelliferous, aquatic European plant, exceedingly poisonous both to man and inferior animals. The root, which has a sweetish not unpleasant taste, is sometimes eaten by mistake for other roots, with the most dangerous effects; and numerous instances of fatal results are on record. The symptoms produced are such as attend irritation or inflammation of the stomach, united with great cerebral disturbance, indicated by giddiness, convulsions, and coma. Externally applied, the root produces redness and irritation of the skin, with an eruptive affection. It is said to be sometimes used empirically as a local remedy in plasters; and a case is recorded in which an obstinate leprosy was cured by the continued use of the juice of the plant. Other species of Enanthe are poisonous, and the whole genus should be regarded among the suspected plants. We have two or three indigenous species. The proper remedies, in cases of poisoning from these plants, are emetics, followed, after the stomach has been thoroughly evacuated, by demulcent drinks. A peculiar resinoid principle, denominated enanthin, has been found by Mr. Gerding in Enanthe fistulosa, of which half a grain, given to an adult, produced long-continued irritation of the fauces, with hoarseness, and a grain occasioned vomiting. (See Am. Journ. of Pharm., xxi. 68.)

GENANTHE PHELLANDRIUM. (Sprengel.) Phellandrium aquaticum. Linn. Fine-leaved Water-hemlock. A biennial or perennial, umbelliferous, European water-plant, the fresh leaves of which are said to be injurious to cattle, producing a kind of paralysis when eaten. By drying, they lose their deleterious properties. The seeds have been used in Europe to a considerable extent in the treatment of disease. They are from a line to a line and a half in length, ovate-oblong, narrow above, somewhat compressed, marked with ten delicate ribs, and crowned with the remains of the calyx, and with the erect or reverted styles. Their colour is yellow-brown; their odour peculiar, strong, and disagreeable; their taste acid and aromatic. By Mr. C. Fronfield it has been rendered probable that they contain a volatile alkaloid, analogous to conia, if it be not conia itself; for if the powdered seeds are rubbed with solution of potassa, the peculiar mouse-like odour of that alkaloid is exhaled. The powder was submitted to distillation with caustic potassa, the alkaline liquid obtained was neutralized with sulphuric acid and evaporated to a syrupy consistency, alcohol was added to precipitate the sulphate of ammonia, the liquid was then filtered, treated with caustic potassa, and again distilled. On the surface of the distillate a yellow oily fluid floated, which was only slightly soluble in water but readily so in ether and alcohol, evinced an alkaline reaction with turmeric paper, and neutralized the alkalies. (Am. Journ. of Pharm., May, 1860, p. 211.) By different writers the seeds are described as aperient, diuretic, emmenagogue, expectorant, and sedative. They probably unite mild narcotic properties with the stimulating powers which are common to most of the aromatics, and may be directed, according to circumstances, to different secretory organs. In overdoses they produce vertigo, intoxication, and other narcotic effects. They appear to have been used most successfully in chronic pectoral affections, such as bronchitis, pulmonary consumption, and asthma. They have been given also in dyspepsia, intermittent fever, obstinate ulcers, &c. The dose of the seeds, to commence with, is five or six grains, so repeated as to amount to a drachm in twenty-four hours. They should be given in powder. A tincture and alcoholic extract have been prepared, of which the former, containing the virtues of half a drachm of the seeds in a fluidounce, is given in a dose varying from half a fluidrachm to a fluidrachm, and the latter in that of three to five grains. (Pharm. Journ., xii. 591.)

GENOTHERA BIENNIS. Tree Primrose. A biennial indigenous plant, growing in fields and along fences from Canada to the Carolinas. It is from two to five feet high, with a rough stem, alternate, ovate-lanceolate leaves, and fine yellow flowers, which make their appearance in July and August. Schoepf states that it is esteemed useful as a vulnerary. The late Dr. R. E. Griffith found a strong decoction of the small branches, with the leaves and cortical part of the stem and larger branches, very beneficial in eruptive complaints, especially tetter. He applied the decoction several times a day to the affected part. He believed the virtues of the plant to reside in the cortical part, which has a mucilaginous taste, and leaves a slight sensation of astringency in the fauces.

OIL OF ANDA. A fixed oil procured by expression from the seeds of Anda Brasiliensis (Radd), Anda Gomesii (Ad. Jussieu), a tree of Brazil, belonging to the family of Euphorbiaceae. The bark yields on being wound a milky juice, which is said to be poisonous, and to be used for stupefying fish. The fruit, which is about as large as an apple, ash-coloured, with two larger and two smaller angles, encloses a two-celled nut, containing two seeds, about the size of a chestnut. Like the seeds of other Euphorbiaceae plants, these are actively purgative; one seed, according to Martius, being the dose for a man. By expression these seeds yield a pale-yellow, transparent oil, with little smell or taste, which

W.
Oil of Ben.—Oil of Jasmine.

PART IX.

is said to be used in Brazil for burning and painting. Dr. Norris, who tried the oil at the Pennsylvania Hospital, found it to operate on the bowels moderately in the dose of fifty drops, and copiously, when more largely given. (Cyclopaedia of Prac. Med. and Surg., i. 470.)

Dr. Alexander Ure, who has experimented with it in several cases, states that, in the average dose of twenty drops, it usually operates mildly, without producing heat or pain in the throat, and seldom causes nausea or vomiting.

OIL OF BEN. This is a fixed oil extracted from the seeds of the Moringa pterygosperma and M. aptera of Gärner, confounded by Linneus under the name of Gulindina Moringa. Hyperanthera Moringa (Vahl) is a synonyme of the former species. These are trees belonging to the family of Leguminose, inhabiting different parts of India, Arabia, Syria, &c., and introduced into the W. Indies. The leaves and other parts have an acrid property, which has probably given the name of horse-radish tree to M. pterygosperma. The oil of the seeds has long been known, though used rather in the arts than in medicine. Most of it is prepared in Europe from the seeds brought from Egypt (Mérat et De Lens); but it is said also to be extracted in the W. Indies. It is inodorous, clear, and nearly colourless, and keeps long without becoming rancid. It is employed for similar purposes with olive oil. Mérat and De Lens say that it is purgative; but most of the fixed oils are so in sufficient doses. According to Völcker, the oil contains margarin, olein, and a peculiar fatty matter yielding an acid by saponification, which he names benic acid. (Journ. de Pharm., xvi. 77.)

OIL OF CADE. Oleum Cedrina. Huile de Cade, French. This is a kind of tar, obtained by distillation, per descensum, from the interior reddish wood of Juniperus communis, or more strictly of J. Orvicedrus, which grows in the south of France, where the substance is prepared. It is a thick liquid, black, and of a smell analogous to that of common tar. It has long been employed in the treatment of the cutaneous diseases of horses, sheep, &c.; and is also applied by the peasantry to their own skin affections. Recently it has acquired much reputation in these complaints, in consequence of its extensive and successful use in the hospitals of Paris. M. Bazin has employed it with success in psora, lichen agris, the different scaly affections, the advanced stage of eczema, and favus. In most of these complaints we have long been in the habit of employing common tar ointment, and with probably equal success. A kind of soap is prepared from the oil of cade, which affords a convenient method of applying it. In the Ed. Monthly Journ. for July, 1852 (page 66), it is stated that the soap is made by distilling the tar, incorporating the volatile oil obtained with a fixed oil, and then saponifying this with soda. It is in the form of black balls, readily unites with water, and may be applied to the surface like any other soap. The best plan is probably to apply it at bedtime, and wash it off next morning. A glycerate of the tar has recently been recommended for external use, made by mixing, with the aid of heat, an ounce of glycerin, half a drachm of the purified oil of cade, and half an ounce of powdered starch. (See Am. Journ. of Med. Sci., Jan. 1859, p. 228.)

OIL OF EUPHORBIA. A fixed oil, obtained from the seeds of Euphorbia Lathyris, a biennial plant growing wild in this country, though believed to have been introduced from Europe. It is often found near gardens and in cultivated fields, and is generally called mole plant, under the impression that moles avoid the grounds where it grows. (Pursh.) It is the caper plant of England. (Loudon's Encyc. of Plants.) Like the other species of Euphorbia, it contains a milky juice, which is extremely acrid; and the whole plant possesses the properties of a drastic purge; but the oil of the seeds is the only part used in regular practice. This may be extracted by expression, or by the agency of alcohol or ether. In the first case, the bruised seeds are pressed in a canvass or linen bag, and the oil which escapes is purified by decanting it from the whitish flocculent matter which it deposits upon standing, and by subsequent filtration. By the latter process, the bruised seeds are digested in alcohol, or macerated in ether, and the oil is obtained by filtering and evaporating the solution. According to Soubeiran, however, the oils obtained by these different processes are not identical. That procured by expression is probably the purest.

Oil of euphorbia is colourless, inodorous, and, when recent, nearly insipid; but it speedily becomes rancid, and acquires a dangerous acrimony. Soubeiran has ascertained that it has a complex composition, containing, besides the pure oil, four distinct proximate principles. (Journ. de Pharm., xxii. 259.) From 40 to 44 parts are obtained by expression from 100 of the seed. It is a powerful purge, operating with much activity in a dose varying from five to ten drops. It was, some years since, much used by certain Italian and French physicians, who did not find it to produce inconvenient irritation of the stomach and bowels. Its want of taste, and the smallness of the dose, recommended it especially in the cases of infants. It was said to be less acrid and irritating than the croton oil, over which it also has the advantage of greater cheapness. Some trials made with it on this side of the Atlantic have not confirmed these favourable reports. It was found uncertain in its cathartic effect, and very liable to vomit. (Scattergood, Journ. of the Phil. Col. of Pharm., iv. 124.) It may be given in pill with the crumb of bread, or in emulsion. W.

OIL OF JASMINE. This oil is obtained from the flowers of Jasminum officinale or cur-
OLIBANUM. Olibanum, the _frankincense_ of the ancients, was erroneously ascribed by Linnaeus to _Juniperus Lycaea_. There appears to be two varieties, one derived from the countries bordering on the Red Sea, and taken to Europe by way of the Mediterranean, the other brought directly from Calcutta. In reference to the tree producing the former there is some uncertainty. Captain Kampthorne, of the E. India Company's Navy, saw it growing upon the mountains, on the African coast, between Bunder MARYAH and Cape Guar- dal. According to his statement, it grows on the bare marble rocks comprising the hills of that region, without any soil or the slightest fissure to support it, adhering by means of a substance thrown out from the base of the stem. This rises forty feet, and sends forth near the summit short branches, covered with a bright-green, singular foliage. The juice, which exudes through incisions made into the inner bark, has at first the colour and consistence of milk, but hardens on exposure. (Pharm. Journ., iv. 37.) Sir W. N. Hooker says that the African olibanum is derived from _Plisssea floribunda_ of Endlicher (Boswellia, Royle), but thinks it highly probable that it is furnished by more than one species. (Ibid., Oct. 1859, p. 217.) The India olibanum has been satisfactorily ascertained to be the product of _Bos- wellia serrata_ of Roxburgh, a large tree growing in the mountains of India, and found by Mr. Colebrook abundant in the vicinity of Nagpur. The tree belongs to the class and order _Decandria Monogynia_, and the natural order _Terebinthaceae_ of Kunth.

The Arabian or African frankincense is in the form of yellowish tears, and irregular reddish lumps or fragments. The tears are generally small, oblong or roundish, not very brittle, with a dull and waxy fracture, softening in the mouth, and bearing much resemblance to mastic, from which, however, they differ in their want of transparency. The reddish masses soften in the hand, have a stronger taste and smell than the tears, and are often mixed with fragments of bark, and small crystals of carbonate of lime.

The Indian frankincense, or olibanum, consists chiefly of yellowish, somewhat translucent, roundish tears, larger than those of the African, and generally covered with a whitish powder produced by friction. It has a balsamical resinous smell, and an acrid, bitterish, somewhat aromatic taste. When chewed it softens in the mouth, adheres to the teeth, and partially dissolves in the saliva, which it renders milky. It burns with a brilliant flame, and a fragrant odour. Triturated with water, it forms a milky imperfect solution. Alcohol dissolves nearly three-fourths of it, and the tincture is transparent. From 100 parts, _Braconnet_ obtained 8 parts of volatile oil, 56 of resin, 30 of gum, and 5-2 of a glutinous matter insoluble in water or alcohol, with 0-8 loss. Various saline substances were found in its ashes. The oil may be separated by distillation, and resembles that of lemons in colour and smell. According to Stenhouse, it is isomeric with oil of peppermint, having the formula C\textsubscript{16}H\textsubscript{20}, and consists of an oxygenous and non-oxygenous oil. (Gmelin's _Hand- book_, xiv. 390.)

Dr. W. F. Daniell has described an odorous product, used as _frankincense_ in Sierra Leone, and obtained from a large tree, growing in the mountainous districts of that region. The tree has been described by Mr. John B. Bennet in the _Pharmaceutical Journal_ for December, 1854 (p. 251), under the name of _Danielia thurifera_. According to Dr. Daniell, the juice exudes through openings made by an insect, and, concreting in connection with the woody particles resulting from the boring of the insect, falls at length to the ground, where it is collected by the negroes. (See _Am. Journ. of Pharm._, xxvii. 338.)

Olibanum is stimulant like the other gum-resins; but is now very seldom used internally. M. Delioux, of Toulon, however, is in the habit of using it for the same purposes as the balsams of Tolu and Peru, having satisfied himself by much experience that it produces similar effects, while it is less costly. He gives it, in the form of pills, in the medium dose of fifteen grains, which may be increased to a drachm or more. It appears to act more favourably when combined with a little soap. He has also obtained advantage from the inhalation of its fumes, when heated, in chronic bronchitis and laryngitis. (Bulletin Général de Thérap., Feb. 28, 1861.) It is chiefly employed for fumigations, and enters into the composition of some unofficious plasters.

ONION. _Cepa_. The bulb of _Allium Cepa_. This is a perennial bulbous plant, with a naked scape, swelling towards the base, exceeding the leaves in length, and terminating in a simple umbel of white flowers. The leaves are hollow, cylindrical, and pointed. The original country of the onion is unknown. The plant has been cultivated from time immemorial, and is now diffused over the whole civilized world. All parts of it have a peculiar pungent odour, but the bulb only is used. This is of various size and shape, ovate, spherical, or flattened, composed of concentric fleshy and succulent layers, and covered with dry mem-
branous coats, which are reddish, yellowish, or white, according to the variety. It has, in a high degree, the characteristic odour of the plant, with a sweetish and acrid taste. Fourcroy and Vauquelin obtained from it a white acrid volatile oil containing sulphur, albumen, much uncrytallizable sugar and mucilage, phosphoric acid both free and combined with lime, acetic acid, citrate of lime, and lignin. The expressed juice is susceptible of the vinous fermentation.

The onion is stimulant, diuretic, expectorant, and rubefacient. Taken moderately it increases the appetite and promotes digestion, and is much used as a condiment; but in large quantities it is apt to cause flatulence, gastric uneasiness, and febrile excitement. The juice is occasionally given, made into syrup with sugar, in infantile catarrhs and croup, in the absence of much inflammatory action. It is also recommended in dropsy and calculous disorders. Deprived of its essential oil by boiling, the onion becomes a mild esculent; and it is much more used as food than as medicine. Roasted and split, it is sometimes applied as an emollient cataplasm to suppuring tumours.

**Opopanax.** The concrete juice of *Pastinaca Opopanax* (Willd.), *Opopanax Chirionum* (De Candolle). This species of parsnip, usually called rough parsnep, has a thick, yellow, fleshy, perennial root, which sends up annually a strong branching stem, rough near the base, about as thick as a man's thumb, and from four to eight feet in height. The leaves are variously pinnate, with long sheathing petioles, and large, oblong, serrate leaflets, of which the terminal one is cordate, others are deficient at their base upon the upper side, and the whole are hairy on their under surface. The flowers are small, yellow, and form large flat umbels at the termination of the branches. The plant is a native of the Levant, and grows wild in the south of France, Italy, and Greece. When the base of the stem is wounded, a juice exudes, which, when dried in the sun, constitutes the opopanax of commerce. Some authors state that it is obtained from the root. A warm climate appears necessary for the perfection of the juice; as that which has been collected from the plant in France, though similar to opopanax, is of inferior quality. The drug is brought from Turkey. It is said to come also from the East Indies; but Ainslie states that he never met with it in any Indian medicine bazaar.

It is sometimes in tears, but usually in irregular lumps or fragments, of a reddish-yellow colour, speckled with white on the outside, paler within, and, when broken, exhibiting white pieces intermingled with the mass. Its odour is strong, peculiar, and unpleasant; its taste bitter and acrid. Its sp. gr. is 1-622. It is inflammable, burning with a bright flame. In chemical constitution it is a gum-resin, with an admixture of other ingredients in small proportion. The results of its analysis by Pelletier were from 100 parts, 33-4 of gum, 42 of resin, 4-2 of starch, 1-6 of extractive, 0-3 of wax, 2-8 of malic acid, 9-8 of lignin, 5-9 of volatile oil and loss, with traces of caoutchouc. Water by trituration dissolves about one-half of the gum-resin, forming an opaque milky emulsion, which deposits resinous matter on standing, and becomes yellowish. Both alcohol and water distilled from it retain its flavour; but only a very minute proportion of oil can be obtained in a separate state.

Opopanax was formerly employed, as an antispasmodic and deobstruent, in hypochondriasis, hysteria, asthma, and chronic visceral affections, and as an emmenagogue in suppression of the menses; but it is now generally regarded as a medicine of very feeble powers, and in this country is scarcely ever used. The dose is from ten to thirty grains.

**ORANGE BRED. Orange Mineral. Sandix.** Red oxide of lead, prepared by calcining carbonate of lead. It is of a brighter colour than minimum, and is used as a pigment.

**ORIGINUM VULGARE. Common Marjoram. Origanum.** This plant was official in the former U. S. and Ed. Pharmacopoeias; but as the volatile oil which was ascribed to it, and for which it was chiefly valued, has proved to be really the oil of thyme, it has been omitted both in the present U. S. and the Br. Pharmacopoeias, though, in consideration of its aromatic properties, it might well have been introduced into the Secondary Catalogue of the former. The genus *Origanum* belongs to Didynamia Gymnospermia in the Linnean system, and to the natural family Lamiaceae or Labiatae, and is characterized as follows. "Strobile four cornered, spiked, collecting the calyces. Corolla with the upper lip erect and flat, the lower three-parted, with the segments equal." (Willd.) Two species have been used in medicine, *O. Majorana*, or sweet marjoram, and *O. vulgare*, or common marjoram. The former grows wild in Portugal and Andalusia, and is cultivated as a garden herb in other parts of Europe, and in the United States. Some authors, however, consider *O. Majoranoides*, which is a native of Barbary, and closely allied to *O. Majorana*, as the type of the sweet marjoram of our gardens. *Sweet marjoram* has a pleasant odour, and a warm, aromatic, bitterish taste, which it imparts to water and alcohol. By distillation with water it yields a volatile oil, which was directed by the Edinburgh College among their preparations. It is tonic and gently excitant, but is used more as a condiment in cookery than as a medicine. In domestic practice, its infusion is much employed by the vulgar to hasten the tardy eruption in measles and other exanthematous diseases.

*Origanum vulgare* or *common marjoram* is a perennial herb, with erect, purplish, downy,
PART III. Orobanche Virginiana.—Oxalic Acid.

four-sided, trichotomous stems, about eighteen inches high, and opposite, ovate, entire, somewhat hairy leaves, of a deep yellowish-green colour. The flowers are of a pinkish-purple or rose colour, disposed in roundish, panicked spikes, and accompanied with ovate reddish bracts, longer than the calyx. This is tubular and five-toothed, with nearly equal segments. The corolla is funnel-shaped, with the upper lip erect, bifid, and obtuse, the lower trifid, blunt, and spreading. The anthers are double, the stigma bifid and reflexed. The plant is a native of Europe and America. In this country it grows along the road-sides, and in dry stony fields and woods, from Pennsylvania to Virginia, and is in flower from June to October; but it is not very abundant, and is seldom collected for use. It has a peculiar, agreeable, aromatic odour, and a warm, pungent taste. These properties it owes to a volatile oil, which was formerly employed, but has been superseded, in great measure, if not altogether, by the oil of thyme. It may be separated by distillation with water. Originum is gently tonic and excitant, and has been used in the form of infusion as a diaphoretic and emmenagogue, and externally as a fomentation; but it is at present little employed.

This is a parasitic, fleshy plant, with a tuberous, scaly root, and a smooth stem, branched from the base, from twelve to eighteen inches high, furnished with small ovate scales, of a yellowish or purplish colour, and wholly destitute of verdure. It is found in all parts of North America, growing upon the roots of the beech tree, from which it obtained its popular name. It is in some places very abundant. The plant has a bitter, nauseous, astringent taste, which is said to be diminished by drying. It has been given internally in bowel affections; but its credit depends mainly upon the idea that it is useful in obstinate ulcers of a cancerous character, to which it is directly applied in the state of powder. The late Professor Barton conjectured that it was an ingredient of a secret remedy, at one time famous as Martin's cancer powder, of which, however, the most active constituent was arsenious acid.

Other species of Orobanche, growing in America and Europe, have been employed. They are all parasitic, fleshy plants, without verdure, and of a bitter, nauseous taste. In Europe they are called broom-rape. The O. Americana and O. uniflora, of this country, are said to be used for the same purposes as the species above noticed, and like it are called cancer-root.

ORPIMENT. King's Yellow. A native tersulphuret of arsenic, consisting of one eq. of metal 79, and three eqs. of sulphur 48 = 123. It is in masses of a brilliant lemon-yellow colour, composed of flexible laminae, and slightly translucent. It exists in various parts of the world, but is obtained for use from Persia and China. (Guibourt.) It is sometimes mixed with realgar, which gives it a reddish or orange hue. A similar sulphuret may be made artificially by passing sulphuretted hydrogen through a solution of arsenious acid in muriatic acid. There is reason to believe that neither the native sulphuret, nor the artificial, when prepared in the manner just mentioned and well washed, is poisonous, at least in a degree at all comparable to other arsenical compounds.

Artificial orpiment is prepared for use by fusing together equal parts of arsenious acid and sulphur. (Turner.) In Germany, according to Guibourt, it is prepared by subliming a mixture of these two substances. In this case, however, it retains a large portion of the acid undecomposed, and is therefore highly poisonous. Guibourt found a specimen which he examined to contain 94 per cent. of arsenious acid, and only 6 per cent. of the tersulphuret.

Orpiment is an ingredient of certain depilatories. Atkinson's depilatory is said to consist of one part of orpiment and six parts of quicklime, with some flour and a yellow colouring matter. (Ann. der Pharm., xxxii. 348.) But this arsenical sulphuret is chiefly used in fire-works, and as a pigment.

ORYZA SATIVA. Rice. This is an annual plant, originally, perhaps, derived from the East Indies, but now cultivated in all parts of the globe where the climate and soil are adapted to its growth. Barth says, in his Travels (Am. ed., 1857, ii. 345), that it grows wild in Central Africa. The rice of commerce consists of the seeds of the plant deprived of their husk. Carolina rice was found by Braconnot to contain 85:07 per cent. of starch, 3:60 of gluten, 0:71 of gum, 0:29 of uncrystallizable sugar, 0:13 of fixed oil, 4:80 of vegetable fibre, 6:00 of water, and 0:40 of saline substances. This grain is highly nutritious, and of easy digestion, and constitutes the almost exclusive diet of whole nations. Being entirely free from laxative properties, it is admirably adapted to cases of weak bowels, in which there is a strong tendency to diarrhoea. Care, however, should be taken that it be boiled till it becomes soft. A decoction of rice, usually called rice-water, is a good nutritive drink in fevers, and inflammatory affections of the bowels, lungs, and kidneys. There appears to be no ground for the opinion, entertained by some, that a diet of rice is injurious to the eyes.

OXALIC ACID. Acidum Oxalicum. This acid is found both in animals and vegetables. It is generated occasionally in consequence of a diseased action in the kidneys, and deposited in the bladder as oxalate of lime, forming a peculiar concretion, called the mulberry calculus. In vegetables, it occurs in a free state in the bristles of the chick-pea (Cicer arietinum), combined with potassa as a supersalt in Rumex acetosa or common sorrel, and Ozalis Acetosella.
Oxalic Acid.

or wood-sorrel, and united with lime in several species of lichen, and in the roots of rhubarb, valerian, and several other plants. It is from the generic appellation *Oxalis* that it takes its name.

**Preparation.** The usual process for obtaining oxalic acid consists in decomposing sugar by nitric acid. Four parts of sugar are acted upon by twenty-four of nitric acid of the sp. gr. 1.24, and the mixture is heated so long as any nitric oxide is disengaged. A part of the carbon of the sugar is converted into carbonic acid by oxygen derived from the nitric acid, which is thereby partially converted into nitric oxide. The undecomposed nitric acid, reacting with the remaining elements of the sugar, generates oxalic and saccharic (oxalhydric) acids, the former of which crystallizes as the materials cool, while the latter remains in solution. The crystals being removed, a fresh crop may be obtained by further evaporation. The thick mother-water which now remains is a mixture of saccharic, nitric, and oxalic acids; and, by treating it with six times its weight of nitric acid, the greater part of the saccharic acid will be converted into oxalic acid. The new crop of crystals, however, will have a yellow colour, and contain a portion of nitric acid, the greater part of which may be got rid of by allowing them to effloresce in a warm place. From the experiments of Mr. L. Thompson, of Newcastle-on-Tyne, it appears probable that, in the reaction occurring between nitric acid and sugar, half the carbon of the latter is converted into carbonic acid, and the other half into oxalic acid.

The manufacturing chemists are said to obtain oxalic acid on a large scale by heating a mixture of 112 lbs. of sugar, 560 lbs. of nitrate of potassa, and 280 lbs. of sulphuric acid. The products are 135 lbs. of oxalic acid, and 490 lbs. of supersulphate of potassa, or *sal enixum*. (L. Thompson.)

Many substances, besides sugar, yield oxalic acid by the action of nitric acid; as molasses, rice, potato starch, gum, wool, hair, silk, and many vegetable acids. In every case in which it is thus generated, the proportional excess of oxygen which it contains, compared with every other organic compound, is furnished by the nitric acid. When the acid is obtained from potato starch, this is first converted into starch sugar by the action of sulphuric acid. The following is an outline of the process, as conducted on a large scale. The pulp of potatoes, obtained by rasping or other suitable means, is washed two or three times by stirring it well with water, allowing it to subside, and running off the water. It is then boiled for some hours with water in wooden boilers, lined with lead and heated by steam; a quantity of sulphuric acid being stirred in the mixture, equal to 2 per cent. of the weight of the potatoes employed. By this treatment the starch of the potatoes is converted into starch sugar; and the change is known to be completed, when a drop of tincture of iodine, added to a little of the boiling liquor, placed on a piece of glass, ceases to produce a purple colour. The product is then filtered through a horse-hair cloth, and the liquid which passes is carefully evaporated until a gallon of it weighs about fourteen pounds. This liquid consists of a concentrated solution of starch sugar, and is now ready for conversion into oxalic acid by the action of nitric acid. For this purpose it is placed in wooden boilers, lined with lead, eight feet square and three deep, and, having been mixed with the requisite proportion of nitric acid, is heated to a temperature of about 125° by means of steam, passed through a coil of lead pipe, until the decomposition is effected. The liquor is then drawn off by a syphon or cock into shallow lead-lined wooden coolers to crystallize. The crystals having formed, the mother-water are drawn off for use in a subsequent operation. When the manufacture of the acid is conducted in vessels of the size just indicated, the density of the nitric acid should not be less than 1:20 nor higher than 1:27. If the nitric acid is used of undue strength, a part of the oxalic acid at first formed becomes converted into carbonic acid, to the no small diminution of the desired product. (Chem. Gaz., March 15, 1852, p. 112.) The product of oxalic acid from a given quantity of saccharine material has been much understated. If properly treated with nitric acid, 100 lbs. of good sugar will yield from 125 to 130 lbs. of oxalic acid, and the same weight of molasses, from 105 to 110 lbs.

Certain organic substances yield oxalic acid when heated with potassa. Thus shavings of wood, if mixed with a solution of caustic potassa, and exposed to a heat considerably higher than 212°, will be partially decomposed, and converted into oxalic acid, which then combines with the alkali. At present much of the oxalic acid of commerce is obtained by heating saw-dust with a mixture of caustic soda and potassa. Soda alone will not generate the acid, and potassa is too costly to be used by itself for the purpose; but Mr. Dale ascertained that, by mixing the two in the proportion of two eqs. of soda to one of potassa, the same result was obtained as from the latter alone. The following is an outline of Mr. Dale's process. A watery solution of the mixed alkalies is evaporated to the sp. gr. 1:35, and then mixed with saw-dust to the consistency of a paste. This is heated on iron plates to 400° F., and kept at this temperature, with constant stirring, for an hour or two. The mass is now dark-coloured, and contains from 1 to 4 per cent. of oxalic acid, with about 0:5 per cent. of formic acid. The heat is continued and extended till the mass becomes quite dry, care being taken that it is not charred. It now contains from 28 to 30 per cent. of oxalic acid. com-
bined with potassa and soda. By washing the powder on a filter with solution of carbonate of soda, the oxalate of potassa is converted into oxalate of soda, and all traces of potassa are washed out. The oxalate of soda is decomposed by heated milk of lime, and the resulting oxalate of lime, by sulphuric acid. The solution of oxalic acid is now evaporated, and yields the acid in crystals. Two pounds of saw-dust afford one of oxalic acid. (See Am. Journ. of Pharm., July, 1863, p. 360.)

As the oxalic acid of commerce often contains more or less of foreign matter, it requires for certain purposes to be purified. M. E. J. Maunené gives the following process for the purpose, which he says answers better than the method generally recommended. The acid is dissolved in sufficient hot water to give on cooling only from 10 to 20 of the crystals, according to the degree of impurity. The first crystals are put aside. The mother-water is then concentrated; and, if the resulting crystals be submitted to two or three successive crystallizations, the acid will be obtained quite free from all alkaline oxalate. (Journ. de Pharm., Feb. 1864, p. 154.)

Properties. Oxalic acid is a colourless crystallized solid, possessing considerable volatility, and a strong, sour taste. Its crystals have the shape of slender, flattened, four or six-sided prisms, with two-sided summits; and, when exposed to a very dry atmosphere, undergo a slight efflorescence. It dissolves in about nine times its weight of cold, and in its own weight of boiling water. The solution of the crystals takes place with slight crepitation. It dissolves also, but not to the same extent, in alcohol. The solubility of nitric acid renders it more soluble in water. It combines with salifiable bases, and forms salts called oxalates. The most interesting of these are the three oxalates of potassa, severally called oxalate, binoxalate, and quadroxalate, and the oxalate of lime. The binoxalate and quadroxalate, both popularly called essential salt of lemons, are employed for removing iron moulds from linen, and act by their excess of acid, which forms a soluble salt with the sesquioxide of iron constituting the stain. Oxalic acid is used for removing ink stains and iron moulds, for cleaning the leather of boot-tops, and for discharging colours in calico-printing.

This acid has a very strong affinity for lime, and forms with it an insoluble precipitate consisting of oxalate of lime, whenever the acid and earth are brought into contact in solution. It is even capable of decomposing fluoride of calcium, evolving hydrofluoric acid. (J. W. Slater.) Oxalic acid and its soluble combinations are the best tests for lime; and, conversely, a soluble salt of lime for oxalic acid. When lime is searched for, oxalate of ammonia forms the most convenient test. So strong is the mutual attraction between this acid and lime, that the former takes the latter even from sulphuric acid. Hence, the addition of a soluble oxalate disturbs the transparency of a solution of sulphate of lime.

Oxalic acid is distinguished from all other acids by the form of its crystals, and by its solution yielding a precipitate with lime-water, insoluble in an excess of the acid.

Composition. Oxalic acid consists of two eqs. of carbon 12, and three of oxygen 24 = 36. Some chemists consider it a dibasic acid, and double these numbers. When crystallized, three eqs. of water 27 must be added, making the eq. of the crystals 63. Two eqs. of this water may be driven off by a regulated heat, by which the acid is made to effloresce, but the third cannot be expelled without destroying the acid itself. Accordingly, anhydrous oxalic acid is not known to exist. From the constitution of oxalic acid thus given, it is plain that this acid corresponds in composition to carbonic acid and carbonic oxide taken together. Notwithstanding that it contains less oxygen than carbonic acid, it is incomparably stronger as an acid, owing probably to some peculiarity in the mode in which its elements are combined. The composition of the acid not only corresponds with the united constituents of carbonic acid and oxide, but there is reason to believe that these two compounds are actually its proximate constituents; for, if treated with strong sulphuric acid, the whole of the water will be abstracted, and the elements of the dry oxalic acid are instantly resolved into equal volumes of carbonic acid and carbonic oxide. Oxalic acid, in combining with salifiable bases, sometimes drops its essential equivalent of water, at other times retains it. Thus the oxalate of lead is a compound of the dry acid and protoxide of lead; while the oxalate of lime retains one equivalent of water.

Medical and Toxical Properties. Oxalic acid, in small doses, largely diluted with water and sweetened to the taste, forms an agreeable, cooling beverage, which may be used in febrile diseases as a substitute for lemonade. M. Nardo recommends it as an antiphlogistic and anodyne remedy in inflammation of the mucous membranes, given in the dose of a grain and a half dissolved in eight fluidounces of liquid. It has been given in phthisis, with the asserted effect of lessening the night-sweats and expectoration, in the dose of half a grain, three or four times a day, increased to a grain. Notwithstanding the safety of its employment in medicinal doses, it is a virulent poison in larger quantities, producing death with great rapidity and certainty. Instances are on record of its proving fatal in ten minutes, and few survive the effects of a poisonous dose beyond an hour. As this acid is generally kept in the shops, and not a few instances are on record of its fatal effects when taken by design, or by mistake for Epsom salt, it is necessary to be somewhat full on its toxical relations.
Oxalic Acid.—Oxalis Acetosella. PART III.

Oxalic acid was first noticed as a poison by Mr. Royston in 1814; since which time it has been investigated in this relation principally by the late Dr. A. T. Thomson, of London, Dr. Percy, of Lausanne, Dr. Coindet, of Geneva, and Dr. Christison, of Edinburgh. Since its properties of certainty and rapidity as a poison have been more generally known, its employment for committing suicide has become more frequent.

From the general resemblance which the crystallized oxalic acid bears to Epsom salt, many fatal mistakes have occurred in consequence of its being sold for that saline purgative. Nothing, however, can be easier than to distinguish them by tasting a minute portion of the suspected substance, which, if oxalic acid, will be found strongly sour, whereas the salt in question is bitter. Unfortunately, however, in the instances of these fatal mistakes, no suspicions being awakened, the solution is swallowed with haste, and the mischief is done before the victim is aware of his danger.

Oxalic acid acts on the economy in two principal ways, according as its solution is concentrated or dilute. When concentrated it causes exquisite pain, followed by violent efforts to vomit, then sudden dulness, languor, and great debility, and finally death without a struggle. When dissolved in twenty times its weight of water, it possesses no corrosive and hardly any irritating power, and is yet a fatal poison, causing death by acting on the brain, spinal marrow, and heart. This statement, however, does not accord with the observations of Dr. Letheby, who asserts that the acid, whether in strong or weak solution, always exercises a corroding or softening power on the animal tissues.

The morbid appearances caused by oxalic acid are various. In a dissection reported by Dr. Christison, the mucous coat of the throat and gullet had an appearance as if scalded, and that of the gullet could be easily scraped off. The inner coat of the stomach was pustaceous, in many points black, in others red, and that of the intestines, similarly but less violently affected. In another case, the whole villous coat of the stomach was either softened or removed, as well as the inner membrane of the oesophagus; so that the muscular coat was exposed, and this coat exhibited a dark gangrenous appearance, being much thickened and highly injected. The stomach usually contains a dark fluid, resembling coffee-grounds, consisting chiefly of altered blood. Dr. Herbert Barker reports a fatal case of poisoning by this acid, in a boy aged sixteen years, in which about a draught of the acid had been taken in the solid state. During life the tongue and lips were unusually pale, but not excoriated. The tongue, after death, was found dotted with white spots. (B. and F. Medico-Chir. Rev., Am. ed., April, 1856, p. 402.) Dr. Snow, of London, has seen a case, in which, after death, the tongue and lips were very white, while the stomach was black. In a few cases no morbid appearances have been discovered.

In the treatment of poisoning by oxalic acid, the remedial measures must be employed with great promptitude. If the antidotes are not at hand, and vomiting is not free, emetics will be proper. The stomach pump would be useful, but no delay in the application of other remedies is admissible in the expectation of its use. Dr. Christison objects to the use of warm water to facilitate vomiting, from a fear that it would increase the danger by favouring the absorption of the poison; but it may be a question whether this evil, considering the incidental benefit of the water in promoting vomiting, is not less than that of the corrosion of the stomach, which copious dilution has a tendency to prevent. The proper antidote is chalk or magnesia, mixed with water; and as soon as either can be procured, it must be administered in large and repeated doses. These substances act by neutralizing the poison, forming with it an insoluble oxalate of lime or of magnesia, both of which are inert. The soluble salts of oxalic acid, as the oxalate of ammonia, and the oxalate of potassa, are likewise poisonous, and the antidotes for them are the same as for the acid.

The best tests for the detection of oxalic acid in the contents of the stomach, or in the vomited matter, in cases of suspected poisoning by this acid, are chloride of sodium, sulphate of copper, and nitrate of silver. The first causes a white precipitate of oxalate of lime, known by its being soluble in nitric acid; the second, a bluish-white precipitate of oxalate of copper; and the third, a dense white precipitate of oxalate of silver, which, when dried and heated, becomes brown and detonates with great violence. When the antidotes have been freely used during life, the poison will be in the state of oxalate either of lime or magnesia. In this case, the oxalate found is to be boiled with a solution of carbonate of potassa, whereby an oxalate of potassa will be generated; and this must then be examined with the reagents above indicated.

B. OXALIS ACETOSELLA. Wood-sorrel. Acetosella. The wood-sorrel is a small, perennial, herbaceous, stemless plant, with numerous radical leaves, which are all sterile, and supported upon slender hairy petioles. The leaflets are obovate, entire, hairy, of a yellowish-green colour, but frequently purplish on their under surface. The scape or flower-stalk, which usually exceeds the petioles in length, is furnished with two scaly bracts near the middle, and terminates in a large white, or flesh-coloured flower, marked with red streaks. The styles are of the same length as the inner stamens. This plant is a native both of Europe and North America. In this country it is found chiefly in the mountainous regions of the interior. It selects shady places, such as woods, groves, and hedges, and flowers in
May. Other indigenous species of Oxalis, more widely diffused than O. Acetosella, might be substituted for it without disadvantage; as they possess similar properties. They all have ternate leaves with obcordate leaflets; and, with the single exception of O. violacea, bear yellow flowers. The whole herbaceous portion may be used.

Wood-sorrel is without smell, and has an agreeable sour taste. It owes its acidity to binoxalate of potassa, which is sometimes separated for use, and sold under the name of salt of sorrel. This is prepared in Switzerland and Germany, from different species of Oxalis and Rumex, by the following process. The plants, previously bruised, are macerated for some days in water, and then submitted to pressure. The liquid thus obtained is mixed with clay, and occasionally agitated for two days. At the end of this time, the clear liquor is decanted, and evaporated so that crystals may form when it cools. These are purified by solution and a new crystallization. Five hundred parts of the plant afford four parts of the acidulous salt. The same salt may be prepared by exactly neutralizing with potassa one part of oxalic acid in solution, then adding one part more of the acid, and evaporating the solution so that it may crystallize upon cooling. Binoxalate of potassa is in rhomboidal crystals, of a sour, pungent, bitterish taste, soluble in forty parts of cold and six parts of boiling water. It contains two parts or two equivalents of oxalic acid, 47.2 parts or one eq. of potassa, and 27 parts or three eqs. of water. Quadraxalate of potassa is often substituted for the binoxalate. It is prepared in the same manner, except that, instead of one part, three parts of the acid are added to the original portion neutralized by potassa. Both salts are kept in the shops under the names of salt of sorrel and essential salt of lemons, and are employed for removing iron mould and ink stains from linen, and sometimes as a test for lime. Both are poisonous, though in a less degree than uncombined oxalic acid.

This and other species of sorrel are refrigerant; and their infusion, or a whey made by boiling them in milk, may be used as a pleasant drink in febrile and inflammatory affections. A solution of the binoxalate of potassa is used, on the continent of Europe, as a substitute for lemonade. The fresh plant, eaten raw, is said to be useful in scurvy. Oxalis crassicaulis, a Peruvian species, yields an edible root, and, by expression from its leaves, a very sour and astrignent juice, which is employed in the form of syrup, in hemorrhages, chronic catarrh, bowel affections, and gonorrhoea, with asserted advantage.

OX-GAIL. Fel Borinum. The bile of the ox is a viscid fluid, of a green or greenish-yellow colour, a peculiar nauseous odour, and a bitter taste. The exact composition of bile is not yet settled. According to Berzelius, it contains, 1. bilin, 2. cholepyrrbin, to which the bile owes its colour, 3. mucus, 4. extractive matters, 5. a peculiar fatty matter, originally found in billary calculi, called cholesterol, 6. oleate, margarate, and stearate of soda, with a little fatty matter not saponified, 7. chloride of sodium, sulphate, phosphate, and lactate of soda, and phosphate of lime. Of these substances, the most abundant and essential is bilin. This, when pure, is uncrystallizable, colourless, translucent, indorod, of an acid and bitter taste with an after-taste of sweetness, inflammable, soluble in all proportions in water and anhydrous alcohol, insoluble in ether, neither alkaline nor acid, and composed partly of nitrogen. One of its most striking properties is the great facility with which it undergoes decomposition; and hence the numerous principles which different chemists have found in bile, many of which are nothing more than metamorphoses of bilin. Under the action of acids, it is changed into two resinous acids called respectively fellinic acid and cholonic acid, into taurin and ammonia. The colouring principle or cholepyrrbin is also readily changed, and gives rise to various new products, among which are biliverdin, a green colouring matter resulting from the absorption of oxygen, and bilifulvin, a yellow colouring matter, which is a double salt of lime and soda with a peculiar azotized acid. (Journ. de Pharm., 3e sér., iii. 177, from the Journ. für praktische Chemie.) E. A. Platner succeeded in separating the chief constituent of bile in a crystalline form, and considered it a compound of soda with a peculiar organic body. Liebig denominated this compound bilate of soda. Among the most recent and authoritative analyses of bile is that of Strecker, whose views differ essentially from those of Berzelius. According to Strecker, the bile of the ox, independently of the colouring, fatty, and saline matters above mentioned, consists essentially of a mixture of a nitroglous acid free from sulphur, which he calls cholic acid (glycocholic acid), and an uncrystallizable, sulphuretted acid also containing nitrogen, denominated choleic acid (taurocholic acid), both of which are combined with soda, constituting a mixture of cholete and choleate of that alkali. These two salts may be separated in the following manner. Dry ox-bile is treated with absolute alcohol, and the tincture precipitated by ether in excess. Both salts are deposited, and the cholate crystallizes upon standing, the choleate remaining in an amorphous form, resembling oily or resinous matter. They may be separated more completely by taking advantage of their different relations to the acetate and subacetate of lead. Both the acids are precipitated by the subacetate, the cholic only by the acetate. If the deposit above referred to be dissolved in water, solution of acetate of lead will throw down a cholate of lead, while the addition of the subacetate of lead to the remainder will precipitate the choleate. The acids may be separated from the salts of
lead by sulphuric acid, and then recombined with soda. Both of the acids are decomposed by the alkalis, with the aid of heat, into choleic acid, which contains neither nitrogen nor sulphur, and into another complex body, which, in the case of cholic acid, is a nitrogenous basic substance named glycocholic (the glycocholic or sugar of gelatin of other chemists), and in that of choleic acid, a neuter substance called taurine, which contains both nitrogen and sulphur, the latter in the extraordinary proportion of 24 per cent. Acids with a boiling heat have an analogous effect, though the nature of the acid produced is different, the cholic acid being resolved into choloic acid and glycocholic, and the choleic into the same acid and taurine. Hence, it has been inferred that the characteristic acids of bile consist of one acid, associated in the cholic with glycocholic, and in the choleic with taurine; so that they have now received the more distinctive names of glycocholic and taurocholic acids, the former nitrogenous, the latter containing nitrogen and additionally two eqs. of sulphur. (See Gregory's Organic Chemistry, 4th ed., Lond., p. 518; also a paper by Dr. J. C. Dalton in the Am. Journ. of Med. Sci., N. S., xxxiv. 305.) Since the examination of bile by Strecker, which ended in these results, further researches have led him to the discovery of other new principles in that part of bile which is soluble both in alcohol and ether. Independent of the fatty matters (glycerides) and cholest erin, he has detected 1. lecithin, a substance previously noticed by M. Gobley, which is resolved under the influence of baryta water into fatty acids, and phosphoglyceric acid, 2. sarcoclastic acid, and 3. an energetic base which he calls cholitin. For the methods of isolating these substances, we must content ourselves with referring to the Journal de Pharmacie (Nov. 1861, p. 374). Besides soda, it is said that there are small but variable quantities of potassa and ammonia combined with the glycocholic and taurocholic acids. In relation to the fatty matters of bile, M. Gobley has shown that they consist of olein, margarin, cholesterin, and especially lecithin, a fatty principle the characters of which were made known by M. Gobley, and that the oleic and margaric acids, generally supposed to exist in bile combined with soda, are the results of the decomposition of the last-mentioned principle, through the influence of putrefaction or chemical reagents. (Journ. de Pharm., xxx. 246.)

Bile was formerly highly valued as a remedy in numerous complaints, and was considered peculiarly applicable to cases attended with deficient biliary secretion. It is supposed to be tonic and laxative. It is prepared for use by evaporating it to the consistency of an extract. The dose is from five to ten grains. Dr. Bonorden has found the most extraordinary effects, in the resolution of hypertrophies, from bile applied directly to the parts affected. Hypertrophy of the mamma and that of the tonsils are particularly mentioned as yielding with surprising facility to this application; but good may be expected from it in all cases of the affection, in which the part can be reached. He employs a mixture of 3 parts of inspissated bile, 1 part of extract of conium, 2 of soda soap, and 8 of olive oil, to be rubbed on the part four times a day. He has also found advantage in similar affections of the eye, as opacity of the cornea, pannus, and staphyloma, from bile dropped into the eye, or applied by a hair pencil, several times a day. (Med. Times and Gaz., Oct. 1858, p. 363.) Refined ox-gall, much used by limmers and painters, is prepared, according to Gray, in the following manner. Take of "fresh ox-gall one pint; boil, skim, add one ounce of alum, and keep it on the fire for some time; to another pint, add one ounce of common salt in the same manner; keep them bottled up for three months, then decant off the clear; mix them in an equal proportion; a thick yellow coagulum is immediately formed, leaving the refined gall clear and colourless." A formula is given in the Br. Pharmacopoeia for purifying bile. (See Pel Bovinum Purificatum, page 1125.)

PÆONIA OFFICINALIS. Peony. This well-known plant is a native of Southern Europe, but is everywhere cultivated in gardens for the beauty of its flowers. The root, flowers, and seeds were formerly official. The root consists of a caudex about as thick as the thumb, which descending several inches into the ground, and sends off in all directions spindle-shaped tubers, which gradually taper into thread-like fibres, by which they hang together. It has a strong, peculiar, disagreeable odour, and a nauseous taste, which is at first sweetish, and afterwards bitter and somewhat acid. The odour is lost, or much diminished by drying. Peony root was in very great repute among the ancients, who used it both as a charm and as a medicine in numerous complaints, particularly epilepsy. In modern times it has also been given in epilepsy and various nervous affections, but is at present seldom used. Dr. A. Livezey, of Lumberville, Penn., states that it is much used in the convulsions of children in his neighbourhood, and bears testimony to its possession of decided nervine powers. (Bot. Med. and Surg. Journ., lv. 407.) The dose of the fresh root is from two drachms to an ounce, boiled in a pint of water down to half a pint, which should be taken daily. It is said to be less active when dried. The expressed juice of the recent root is recommended in the dose of an ounce. It is milky, of a strong odour, and very disagreeable taste. The flowers are usually of a deep-red colour, though in some varieties of a light-red, and even whitish. They have, when fresh, an odour similar to that of the root, but feebler, and an astringent, sweetish, herbaceous taste. When dry they are inodorous. As a medicine they have little power. The seeds are roundish-oval, about as large as a pea, externally smooth, shining.
and nearly black, internally whitish, inodorous when dry, and of a mild, oleaginous taste. By some authors they are said to be emetic and purgative, by others antispasmodic. They may be given in the same dose with the root, but are not used in regular practice. W.

Palm Oil. This highly valuable fixed oil is the product of Elaiia Guineensis, a palm growing on the western coast of Africa, and cultivated in the West Indies and South America. It is among the handsomest of its graceful family which flourish in the tropical regions of Africa. The oil is obtained by expression from the fruit. It is brought to this country chiefly from Liberia and other places on the African coast, though prepared also in the West Indies, Cayenne, and Brazil. It is not improbable that various species of palms contribute to the supply of this article of commerce.

Palm oil has the consistence of butter, a rich, orange-yellow colour, a sweetish taste, and an agreeable odour, compared by some to that of violets, by others to that of the Florentine orris. By age and exposure it becomes rancid and of a whitish colour. It melts with the heat of the hand, and when perfectly fluid passes readily through blotting paper. Highly rectified alcohol dissolves it at common temperatures, and in ether it is soluble in all proportions. According to M. Henry, it consists of 81 parts of stearin and 69 of olein. But, from the experiments of Frémy and Stenhouse, it appears that the stearin has peculiar properties entitling it to be considered as a distinct principle; and it has accordingly received the name of palmitin. This is converted into palmitate acid by saponification. (Kane's Chemistry.) It appears also that a considerable proportion of this acid, together with some glycerin, exists uncombined in the oil, as ascertained by MM. Pelouze and Boudet; so that the changes which are effected in oils, through the agency of alkalies, in the process of saponification, take place to a great extent, spontaneously, in palm oil. (Journ. de Pharm., xxiv. 289.) Hence it is more easily saponified than any other vegetable oil. Preparatory to saponification, it may be bleached rapidly, according to J. J. Pohl, by heating it quickly to 464° F., and keeping it for ten minutes at that temperature. It loses for a time its peculiar odour by the process, acquiring an empyreumatic smell; but this after a while ceases to be perceived, and the characteristic odour returns. (See Am. Journal of Pharm., xxvii. 346.) Palm oil is said to be frequently imitated by a mixture of lard and suet, coloured with turmeric, and scented with Florentine orris. It is much employed in the manufacture of a toilet soap, which retains its pleasant odour. Palm oil is emollient, and has sometimes been employed in friction or embrocation, though not superior for this purpose to many other oleaginous substances. W.

Parietaria Officinalis. Wall Pelitory. A perennial European herb, growing on old walls and heaps of rubbish. It is inodorous, has an herbaceous, somewhat rough and saline taste, and contains nitre derived from the walls where it flourishes. It is diuretic and refrigerant, and is said also, but without good reason, to be demulcent and emollient. The ancients employed it in various complaints, and it is still considerably used on the continent of Europe, especially in domestic practice. It is given in complaints of the urinary passages, dropsy, and febrile affections, usually in the form of decoction. The expressed juice is also used, and the fresh plant is applied in the shape of a cataplasm to painful tumours. W.

Parthennium Integrilofilium. Prairie Dock. This is an herbaceous perennial, growing abundantly in the prairies of our South-western States. It is recommended by Dr. Mason Houlton as a powerful antipertiodic. The flowering tops are the part used. They have an intensely bitter taste; and two ounces of them in the dried state, given in the form of infusion, are thought by Dr. Houlton to be equivalent to twenty grains of sulphate of quinine. Thirty successive cases of periodic fever were cured by this remedy, without any unpleasant effect on the nervous system. (Med. Exam., N. S., ix. 710, from Memphis Med. Recorder; and Pharm. Journ., xii. 902, from N. Y. Journal of Pharm.) W.

Patent Yellow. Mineral Yellow. A pigment, consisting of chloride combined with protoxide of lead. It is prepared by mixing common salt and litharge with a sufficient quantity of water, allowing the mixture to stand for some time, then washing cut the liberated soda, and exposing the white residue to heat. W.

Paulinia. Guarana. This is a new medicine introduced into Europe from Brazil, which has attracted some attention from the asserted fact, that it contains a principle identical with caffein. The name of paulinia has been bestowed upon it from the generic title of the plant from which it is obtained. That of guarana, by which it was previously known, was derived from a tribe of aborigines, called Guaraniis, who are said to use it extensively as a corrigent of their vegetable diet. It is prepared from the seeds of the Paulinia sorbilis of Martius, a climbing shrub, belonging to the class and order Octandria Trigynia of the Linnean system, and the natural family of the Sapindaceae. Another species, the P. Cupana, growing on the banks of the Orinoco River, is also said to yield it. (Ann. de Léthrop., 1858, p. 70.) The seeds, which are contained in a three-celled, three-valved, coriaceous capsule, are lenticular and almost thorny, and invested with a flesh-coloured arillus, which is easily separable when dry. They are prepared by powdering
them in a mortar, or upon a chocolate stone previously heated, mixing the powder with a little water, exposing it for some time to the dew, then kneading it into a paste, mixing with this some of the seeds either whole or merely bruised, and finally forming the mixture into cylindrical or globular masses, which are dried and hardened in the sun, or by the smoke of a fire. These masses are of a reddish-brown colour, rugose on the surface, very hard, and of a marbled appearance when broken. Paullinia is of a somewhat astringent and bitterish taste, and, in this as well as in its odour, bears some resemblance to chocolate, though not oleaginous. It swells up and softens in water, which partially dissolves it. Martin found in it a crystallizable principle, which he named guaranin, but which has been proved by M. Berthemot and Dechastelus to be identical with caffeine. The discovery of caffeine in four plants belonging to distinct natural families, namely, the coffee and tea plants, the Paraguay tea, and the Paullinia, is a highly interesting result of recent chemical investigations. It is said to be more abundant in the Paullinia than in either of the other vegetables; 5-07 per cent. having been found by Dr. Stenhouse in paullinia, while he got only 2-13 from good black tea, 1-00 per cent. from coffee, and 1-2 from Paraguay tea. (Pharm. Jour., xvi. 213.) According to Berthemot and Dechastelus, it exists in the seeds united with tannic acid, with which it appears to form two compounds, one crystallizable and soluble in water, the other of a resinoid appearance and insoluble. Besides these ingredients, the seeds contain also free tannic acid, gum, albumen, starch, and a greenish fixed oil. (Journ. de Pharm., xxvi. 514.) More recently M. Fournier has found in paullinia, besides tannate of caffeine, the following principles; gum, starch, an acrid green fixed oil, a concrete volatile oil, an aromatic liquid volatile oil soluble in water with a little alcohol, another liquid volatile oil scarcely soluble in water, a peculiar principle not precisely determined, and tannic acid. (Ibid., April, 1861, p. 201.)

It is said to have been by mistake that paullinia and guarana have been considered identical; the former term being applicable exclusively to the product of the two species of Paullinia above referred to, while the latter belongs properly to a preparation made by the aborigines, which, though it contains the seeds of the Paullinia, is a mixture of various substances, among them chocolate and farina, but the precise composition of which is most carefully kept secret by the natives. (Ann. de Thérap., 1858, p. 70.)

The effects of paullinia upon the system are said to be those of a tonic; but they do not appear to have been very accurately investigated. It is highly probable, both from its composition and the use made of it by the natives of Brazil, that it has an influence upon the nervous system similar to that of tea and coffee. It is habitually employed by the Indians, either mixed with articles of diet, as with cassava or chocolate, or in the form of drink, prepared by scraping it, and suspending the powder in sweetened water. It is considered by them useful in the prevention and cure of bowel complaints. Dr. Cavrelo, who was formerly physician to Don Pedro, in Brazil, and there became acquainted with the virtues of this medicine, called the attention of the profession to it some years since in France. He had found it advantageous in the diarrhoea of phthisis, sick-headache, paralysis, tedious convalescence, and generally as a tonic. By Dr. Ritchie, Surgeon in the British navy, it is highly recommended in irritation of the urinary passages. (Ed. Month. Journ. of Med. Sci., N. S., v. 407.) Dr. Hervé has been in the habit of using it daily for five or six years, and has never failed to derive advantage from it in idiopathic diarrhoea, even in the most obstinate cases. (B. and F. Med.-Chr. Rev., Jan. 1858. p. 192.) It may be given in substance, in the quantity of one or two drachms, scraped into powder and mixed with sweetened water; but the most convenient form of administration is that of spirituous extract. According to M. Dechastelus, alcohol is the only agent which completely extracts its virtues; ether and water effecting this object but partially. Of the extract eight or ten grains may be given during the day in the form of pill. Paullinia may also be taken along with chocolate as a drink.

PEACH LEAVES. Leaves of Amygdalus Persica. (Willd. Sp. Plant. ii. 982.) Persica vulgaris. (Miller, Lamarc.) Every one is familiar with the appearance of the common peach tree. It is characterized specifically by having "all the serratures of the leaves acute, and by its sessile solitary flowers." Though its native country is not certainly known, it is generally supposed to have been brought originally from Persia. In no country, perhaps, does it attain greater perfection, as regards the character of its fruit, than in the United States. Peaches are among the most grateful and wholesome of our summer fruits. They abound in saccharine matter, while the pulp and the juice suscitate the vivifying action, and a distilled liquor prepared from them has been much used, in some parts of the country, under the name of peach brandy. The kernels of the fruit bear a close resemblance in appearance and properties, and probably in chemical nature, to bitter almonds, for which they are frequently prepared in the preparation of liqueurs, and by cake-bakers to give flavour to various productions of their ovens; and are said to yield as much amygdalin as bitter almonds. The flowers, leaves, and bark also have the peculiar odour and taste of bitter almonds, and yield hydrocyanic acid. The leaves afford a volatile oil by distillation. The distilled water
Pearl White.—Peroxide of Hydrogen.

prepared from them was found, in one instance, to contain 1-407 parts of hydrocyanic acid in 1000, and in another only 0·437 parts in the same quantity. From some experiments it may be inferred that the proportion of acid is greatest where there is the least fruit. (See Am. Journ. of Pharm., xxiv. 172.)

Medical Properties. Peach leaves are said to be laxative; and they probably exert, to a moderate extent, a sedative influence over the nervous system. They have been used as an anthelmintic with great reported success. More recently their infusion has been recommended in irritability of the bladder, in sick stomach, and hooping-cough. Half an ounce of the dried leaves may be infused in a pint of boiling water, and half a fluidounce given for a dose three times a day, or more frequently. Dr. Dougis gives, in hooping-cough, a pint of the strong infusion, in small doses, in the course of the day. (Journ. de Pharm., xxiii. 396.)

The flowers are also laxative; and a syrup prepared from them is considerably used, in infantile cases, upon the continent of Europe. Woodville states that a drachm of the dried flowers, or half an ounce in their recent state, given in infusion, is the dose as a vermifuge. Cases of fatal poisoning from their use in children are on record. The kernels have more of the peculiar powers of hydrocyanic acid, and therefore require to be used with some caution. Blanched, and rubbed up with hot water, they form an emulsion well adapted to coughs depending on or associated with nervous irritation. The bruised leaves, flowers, or kernels may be used by the apothecary for cleansing his vessels from disagreeable odours. (See page 101.)

The dried fruit, stewed with sugar, is an excellent laxative article of diet, suitable to cases of convalescence attended with torpid bowels.

PEARL WHITE. Pearl Powder. This is identical with the subnitrate of bismuth, described at page 1025, and is made by adding a solution of the ternitrate of toeroxide of bismuth to distilled water. It is used as a cosmetic.

PELARGONIUM ODORATISSIMUM. Rose Geranium. This well-known plant, so much a favourite for its odour in our dwellings and conservatories, is a native of the Cape of Good Hope, but is said to be cultivated extensively in the south of France and in Turkey for the sake of its volatile oil, which is much employed for the adulteration of the oil of roses. According to Goulbourn, three species of Pelargonium yield a volatile oil by distillation, closely analogous in smell to that of the rose; the species above named, P. capitatum, and P. roseum. (Hist. Nat. des Drogues, 4e ed., iii. 52.) The oil is obtained from the leaves. M. Reclus obtained from 35 ounces of P. odoratissimum two drachms of a volatile, crystallizable oil. (Mérai et De Lens, Dict. de Mat. Méd., iii. 398.) According to Septimus Piesse, 1 cwt. yields about two ounces. (See Am. Journ. of Pharm., xxvi. 365.) As we have seen the oil in our shops, purporting to be the oil of P. odoratissimum, it is perfectly fluid at ordinary temperatures, of a pale brownish-yellow colour, and the characteristic smell of the plant, recalling merely that of the rose. Gregory states that pelargonic acid was first obtained from the oil of P. roseum, which is probably the same as that under consideration. (Organic Chem., 4th ed., Lond., p. 274.) This oil is now much used in perfumery, and, dissolved in alcohol to the proportion of three ounces to the gallon, forms the preparation called "rose-loof gum." Mr. Piesse states, that, as this oil is used to adulterate that of roses, so is it in its turn adulterated with the cheaper oil of Andropogon nardus, cultivated in the Moluccas. (Am. Journ. of Pharm., xxvi. 365.)

PEROXIDE OF HYDROGEN. This substance, though long known to chemists, has but recently been brought into notice as a remedy. It consists of water in which, by the presenting to it of oxygen in a nascent state, an additional equivalent of this element has combined with the hydrogen forming the deutoxide (HO). It was discovered by Thenard in 1818. To prepare it, peroxide of barium is rubbed with distilled water so as to form a liquid paste, which is added gradually, with constant stirring, to distilled water acidulated with one-third of its weight of muriatic acid, contained in a vessel immersed in a freezing mixture. The peroxide of barium (BaO) gives up one of its eqs. of oxygen to the eq. of water (HO), forming an eq. of deutoxide or peroxide of hydrogen (HO₂); while the protodeoxy of barium left reacts with an eq. of muriatic acid to form one eq. of chloride of barium and one of water. When the muriatic acid is saturated, a fresh quantity of the acid in a concentrated state is added, and then more of the peroxide of barium; and the operation is repeated till the solution will hold no more chloride of barium. It is then immersed in a mixture of ice and salt, and the greater part of the chloride of barium is deposited. The portion remaining in solution may be got rid of by the cautious addition of sulphate of silver, which precipitates sulphate of baryta and chloride of silver. The liquid being now filtered, is concentrated by exposing it in vacuo in a shallow vessel placed over another containing sulphuric acid. The water rises in vapour which is absorbed by the acid, and at last the peroxide of hydrogen is left nearly pure. (Regnault.) Thus procured it is a colourless liquid of a fluid consistence, of the sp. gr. 1·452, remaining liquid at zero, beginning to give out oxygen when heated above 60°, and at a higher heat rapidly and sometimes explosively resolved into water and oxygen. But when diluted with water, with which it unites in all proportions, it is not decomposed under 100°. The great facility
with which it parts with oxygen renders it a powerful oxidizer; and the simple contact with various substances, as platinum, gold, and silver, causes it to be resolved into oxygen and water. On the contrary, certain other substances, even though ordinarily evincing a strong affinity for oxygen, as phosphorus, for example, are unaffected by it, and there is a large number of bodies, as ammonia, hydrocyanic acid, tobacco, acouite, and most other narcotic substances, which have the property not only of being unaffected by it, but of restraining its oxidizing influence on other bodies. Its relations to ozone are peculiar; and at one time it was conjectured that ozone was nothing else than peroxide of hydrogen. At present the oxygen in it is considered by some as in the positive state and called ozone, while ozone itself is oxygen in the negative state, and the two mixing produce oxygen in its ordinary state or neutral oxygen. When this neutral condition of oxygen is disturbed, giving rise to the phenomena of ozone, antozone is also liberated. Hence, according to Schönbein, whenever, upon the contact of phosphorus with water, ozone appears, the water is found to contain peroxide of hydrogen. These facts may at some future time prove to have an important bearing on peroxide of oxygen as a physiological or remedial agent; but at present they may be left out of view in treating of it medicinally.

The profession is indebted to Dr. B. W. Richardson, of London, for what is known of the physiological operation and therapeutic effects of peroxide of hydrogen. In relation to its influence on organic bodies, Dr. Richardson found that to venous blood, deprived of its fibrin, it imparts oxygen, with an increase of heat, and a change of the colour to red. Fibrin and cellular tissue cause it to evolve oxygen. Sugar and starch are decomposed by it, giving out carbonic acid. Albumen, gelatin, urea, and cutaneous tissue have no effect on it. Injected into the left cavities of the heart of an animal, it restores the irritability of that organ, but has an opposite effect in the right cavities. Thrown into the arteries, immediately after death, it restores for a time the contractile power of the muscles, and suspends cadaveric rigidity, while it counteracts the influence of various medicinal substances that cause muscular spasm. Dr. Richardson inferred from his experiments that the peroxide might be found useful as an antidote to the narcotic poisons, as a local application to gangrenous ulcers, and as an internal remedy in low forms of fever. Subsequently, from numerous therapeutic trials of the remedy, he came to the conclusion, that it is of great value in chronic and subacute rheumatism; acts in the removal of scrofulous tumours like iodine; relieves the paroxysms of hooping-cough, and cuts short the disease more effectually than any other medicine; affords great relief in chronic bronchitis with dyspnée; and, in phthisis, operates favourably in the early stage by improving digestion and giving increased activity to chalybeate remedies, while, in the advanced stages, it afforded great relief to the dyspnée and oppression, acting, indeed, in this respect, like opium without its narcotic effects. In general, it seemed to him to improve digestion, and therefore to be useful in cases complicated with dyspepsia. Sometimes, when freely employed, it produced profuse salivation, suggesting the idea that it might in other respects resemble mercury, and possibly be found capable of replacing this remedy to a certain extent in the treatment of disease. Dr. Richardson recommends that a solution of the peroxide should be used charged with ten volumes of oxygen, the dose of which may be from one to four fluidrachms, freely diluted with water. There are so many substances which decompose the peroxide, that, as a general rule, it is best given without addition; at least nothing should be allowed to remain long in contact with it. There can be no difficulty in obtaining the desired strength of ten volumes of oxygen to one of the solution, by estimating the quantity of oxygen contained in the peroxide of barium employed in the process. (See Lancet, Oct. 20, 1860, and April 12, 1862.)

PETROLEUM. Rock Oil. This was recognised by the late London and Edinburgh Colleges, but has been omitted in the British Pharmacopœia, and, as it holds no place in that of the United States, takes rank among the extra-official medicines. Petroleum belongs to the class of native inflammable substances, called bitumens. These are liquids or readily fusible solids, which emit, when heated, a peculiar smell, burn easily, and leave a very small carbonaceous residue. They exist in nature either isolated, or combined with carbon in various proportions, forming the different kinds of bituminous coal. Formerly the lighter coloured, purer, and more liquid forms of petroleum were distinguished by the name of naphtha, which was defined to be a transparent, yellowish-white, very light and inflammable, limpid liquid, of the bituminous character; but as this name has been conferred of late on the lighter liquid resulting from the distillation of coal tar or petroleum at a comparatively low temperature, and as there is no sufficient line of distinction between the native naphtha and the impure forms of rock oil, it is, we think, desirable that the name should be confined to the artificial product, while the term petroleum is considered as embracing all the native liquid substances belonging to this class. When the bitumen is in the solid state it is called asphaltum. This is black, dry, friable, and insoluble in water or alcohol. Not unfrequently asphaltum exists in nature mixed with more or less of the liquid substance; and this semi-solid mixture is distinguished by the name of maltha or mineral tar. Exposed to the air, petroleum gradually passes into the state of asphaltum. W.
Petroleum has been known from the earliest historical period. Herodotus refers to wells of it existing in Zante, and from time immemorial it has been known in Persia, where it was probably connected with the origin and ceremonies of fire-worship. Till recently the best-known sources of it were the borders of the Caspian Sea in Persia, at Amiano in Italy, at Gabian in France, the island of Trinidad in the West Indies, and in the Burman Empire near Rangoon, where vast quantities have been annually raised for many centuries, with out any apparent exhaustion of the wells from which it was drawn. Within the limits of the United States it has long been known to exist in a few localities. On the borders of Seneca Lake in the State of New York, small quantities of it were collected, and to some extent used in medicine under the name of Seneca oil. In Western Pennsylvania, on Duck Creek in Ohio, near Scottsville in Kentucky, and on the Kenhawa in Virginia, it attracted some local attention; and a certain locality in Western Canada had acquired some notoriety by its burning spring. But little attention was paid to it until about eight years since; when, the preparation of oil for burning, distilled from coal tar, having proved very profitable, and a strong resemblance if not identity having been proved to exist between this and petroleum, enterprise was directed towards some of the known sources of the latter liquid, which was greatly stimulated by success, and soon led to further and astonishing discoveries. Hitherto the most productive locality of rock oil has been in Western Pennsyl-

vania; but it has been found to exist in great quantities elsewhere, and in fact occupies great portions of a region commencing in Western Canada, and extending, through New York and Pennsylvania, westward into Ohio and Kentucky, and far southward into Western Virginia. From the latest accounts it appears that petroleum exists also abundantly in Cal-

ifornia, and promises to vie with gold as a source of wealth to that country. Establishments for purifying the petroleum have multiplied with great rapidity, and the quantity of oil collected, and either exported or consumed at home, would be incredible, considering the short time since the trade in it may be said to have begun, were it not attested by positive returns. The quantity of petroleum exported, either crude or refined, independently of that consumed in this country, from the ports of Boston, New York, Philadelphia, and Baltimore, amounted in 1862 to 10,887,701 gallons; in 1863, to 28,250,721; and in 1864, to 31,772,972.

(N. Y. Times, Feb. 16, 1865.)

Petroleum sometimes exists in overflowing springs, as in Canada, N. W. Virginia, and very largely in California, issuing along with the water, and spreading itself over the surface of streams for a considerable distance. It is, however, much more abundantly obtained by digging or boring wells. In this case, if the point struck be below some underground reser-
voir of the oil, it may rise, as in artesian wells, to the surface. Sometimes it is driven up with considerable though variable force, probably by the expansive power of compressed gas, which not infrequently escapes along with the oil, and in some places so copiously and steadily as to be used for lighting purposes in the immediate vicinity: the gas being some form of carburetted hydrogen. But in most instances it is necessary to raise the oil by pumps. The distance at which it is found beneath the surface is very different, the depth of boring in Western Pennsylvania varying from 71 to 600 feet. (D. Murray, Trans. Albany Instit., iv. 140.) It is necessary to bore through an overlying rock before reaching it. The oil is generally collected in the fissures and pores of some spongy rock as sandstone or shale. Its original source was probably an underground distillation of vegetable matter, carried on upon a vast scale by nature, by means of subterranean heat. Its close resem-
bliance to the tar resulting from destructive distillation of organic matter can be explained only upon this supposition.

Crude petroleum is variable in character, being sometimes transparent and of an amber colour, but more generally brown or almost black and opaque in mass, or of various shades between the two, in some instances very thin and mobile, in others thicker, and occasionally almost semi-solid, of a peculiar characteristic odour, always lighter than water, and in great measure volatile by heat. A specimen of Pennsylvania petroleum, fresh from the wells, was found by Mr. E. S. Wayne, of Cincinnati, to have the sp. gr. 0.810, which, however, after the petroleum had been exposed to the air for 24 hours, rose to 0.825. When subjected to fractional distillation, it yielded liquid products varying in sp. gr. from 0.668 to 0.825; the lightest coming over first. The paraffin obtained from this petroleum Mr. Wayne believes to be very different from that obtained from coal tar, having both a lower boiling point and lower sp. gr., and, besides, differing in chemical constitution. (The Druggist, Cincin-

nati, June 18, 1860.) In the purer form of naphtha, petroleum is a carbonydron, and, on account of the absence of oxygen, has been used for the preservation of potassium. The crude oil consists of a large number of distinct substances, generally carboydrons of various sp. gr. and boiling points, which may be separated by distillation, and by the action of sulphuric acid and soda or potassa. Mr. Schreinemakers, as the result of his examination of refined American petroleum, the product of the first rectification, that it contains benzol and toluid in small proportion, but consists mainly of hydrides (hydrures) of the alcohol radicals, of which he isolated four; namely, hydride of amyl, C_{10}H_{22}O, boiling at 92° F.; hydride of hexyl, C_{11}H_{26}O, boiling at 104° F.; hydride of heptyl, C_{14}H_{30}O, boiling at
209° F., and hydride of octyl, C_{16}H_{31}+, boiling at 236°. (Chem. News, April 4, 1863, p. 157.) MM. Pelouze and Cahors have isolated seven distinct carbohydrogens from rectified American petroleum, of a lower boiling point than 392° F., viz., butyl hydride C_{11}H_{19}, amylo hydride C_{10}H_{19}, caproyl hydride C_{9}H_{18}, amantyl hydride C_{9}H_{18}, caproyl hydride C_{8}H_{16}, pelargonyl hydride C_{7}H_{16}, and caproyl hydride C_{6}H_{16}. (Ibid., April 25, 1863, p. 197.)

**W.** Barbadoes petroleum is a black, nearly opaque, inflammable liquid, of the consistence of molasses, unctuous to the touch, and possessing a bituminous taste, and strong and tenebrous odour. Its sp. gr. varies from 0·730 to 0·878. When subjected to distillation it yields naphtha, and leaves a solid residue of asphaltum. It is little affected by alcohol, acids, or alkalies, but dissolves in ether and in the fixed and volatile oils. It consists chiefly of carbon and hydrogen, associated with a little nitrogen and oxygen. Rangoon petroleum, also called Rangoon tar and Burmese naphtha, has a greenish-brown colour, a peculiar, rather fragrant odour, and the consistence of goose-fat. It is lighter than water. Heated to 90° it becomes a very mobile liquid. By distilling it in a current of steam, first at 212°, and afterwards super-heated, Drs. W. De la Rue and H. Müller obtained 96 per cent. of volatile products, solid and liquid. The solid product (varaffin) amounted to from 10 to 11 per cent., and was found resolvable by these chemists, by fractional crystallization from hot alcohol, into at least two polymeric carbohydrogens, having the probable formula C_{10}H_{n}. The liquid product, usually called naphtha, is separable by sulphuric and nitric acids into two sets of carbohydrogens; one set removable by these acids, the other resisting their action. The former set contain fewer eqs. of hydrogen than of carbon, and embrace, among other carbohydrogens, benzole and toluene. The latter, which form by far the larger portion of the liquid product, are perfectly colourless, almost inodorous, very mobile liquids, not congealable by intense cold. Their probable formula, according to Drs. De la Rue and Müller, is C_{4}H_{n}+. (See Chem. Gaz., Oct. 1, 1856, p. 375.)

**B.** The method of purifying petroleum is very nearly the same as that already described for purifying coal tar. The following description is taken chiefly from a communication of Mr. David Murray to the Albany Institute, Dec. 1862, and published in its Transactions (vol. iv. p. 149). Much water is often pumped up with the petroleum, but separates from it on standing, the oil rising to the surface. The crude oil is put into large retorts of cast or wrought iron and exposed to a heat between 600° and 800°, by which all the volatile ingredients are distilled, leaving 10 or 12 per cent. of solid residue, constituting a sort of coke. The liquid thus obtained is comparatively colourless, though still retaining the strong odour of the crude oil. To separate various organic alkaloids and acids with which it is mixed, the distilled petroleum is agitated first with sulphuric acid, and afterwards with a strong solution of soda or potassa; the sulphuric acid with its dissolved impurities being drawn off, and the oil well washed with water, before the addition of the alkali, and afterwards again washed when the alkali has performed its function. The purified petroleum is now submitted to another distillation, but at first at a temperature not exceeding 120° (Murray), in order that only the more volatile carbohydrogens may be driven over, which are unsuitable for lamp-oil. These, being condensed, constitute what is now commonly called naphtha, which is used as a solvent for varnishes and caoutchouc, and for mixture with paints, a purpose which it answers as well as oil of turpentine, except for its offensive smell. It is unsuitable for lamps from its extreme volatility, its liability to smoke when burned, and the danger of explosion from the admixture of its vapour with atmospheric air. After the naphtha, which is equivalent to the benzine of coal tar, has all come over, the heat is increased and the distillation continued until the distilled liquid attains the sp. gr. 0·820. This is the part sold for lighting, and is by far the most important product of petroleum. The quantity of it obtained varies greatly, sometimes not exceeding 30 per cent., sometimes amounting to 80 or 90. It is clear, and of a fine deep amber colour, and answers admirably for lighting, yielding a brighter and purer flame than perhaps any other kind of lamp-oil. If the distillation be now continued, a darker and heavier product comes over, which upon cooling deposits paraffin. The part remaining liquid, which is too impure for burning, is employed for lubricating machinery.

**W.** Medical Properties and Uses. Petroleum is accounted a stimulating antispasmodic, expectorant, and diaphoretic. It is occasionally given in disorders of the chest, when not attended with inflammation. In Germany it has been extolled as a remedy for tape-worm. Schwartz’s formula in such cases was a mixture of one part of petroleum with one and a half parts of tincture of assafetida, of which forty drops were given three times a day. Externally, petroleum is employed in chilblains, chronic rheumatism, affections of the joints, paralysis, and diseases of the skin. It is an ingredient in the popular remedy called British oil. (See note, p. 602.) The dose of Barbadoes petroleum is from thirty drops to a small teaspoonful, given in any convenient vehicle. Rangoon petroleum is probably more active, and should be given in a smaller dose. The New York petroleum, called Seneca oil, is used to a considerable extent as an external application in domestic practice. It is lighter coloured, thinner in consistence, and less sapid and odorous than the Barbadoes petroleum, and probably contains more naphtha. The finer kinds of petroleum, called naphtha, have
been used with advantage in epidemic cholera by Dr. Andreosky, of the Russian army, by M. Cloquet, physician to the Shah of Persia, and by M. Moretin, of France. They gave from ten to twenty drops in half a glass of white wine or mint water.

PHLORIDZIN. This is a bitter principle, discovered by Dr. Konink, of Germany, in the bark of the apple, pear, cherry, and plum trees. It is most abundant in the bark of the root, and derived its name from this circumstance (from two Greek words, πυρις, bark, and ιτίν, a root). It is light, white, crystallizable in silky needles, of a bitter taste, soluble in about 1000 parts of cold and in all proportions in boiling water, very soluble in alcohol, scarcely soluble in either cold or hot, dissolved without change by solutions of the alkalies, especially by ammonia, deprived of its water of crystallization at 212°, and fusible at a somewhat higher temperature. It is without acid or alkaline reaction, and consists of carbon, hydrogen, and oxygen; its formula, being, according to G. Roser, when dry, $C_{4}H_{2}O_{5}$, with the addition of 4 eqs. of water when crystallized. When heated with dilute muriatic or sulphuric acid, it is converted into sugar and a peculiar substance called phloretin. (See Chem. Gaz., viii. 392.) To obtain it, the fresh bark of the root of the apple tree should be selected, as the dried bark is said to contain it in much smaller proportion. The bark is to be boiled for an hour or two successively in two separate portions of water, each sufficient to cover it, and the decoction set aside. At the end of thirty hours they will have deposited a considerable quantity of coloured phloridzin, which may be purified by boiling for a few minutes with distilled water and animal charcoal, filtering, repeating this process two or three times, and then allowing the solution to cool slowly. The phloridzin is deposited in the crystalline state. An additional quantity may be obtained by evaporating the decoction to one-fifth of its bulk, allowing it to cool, and purifying the substance deposited in the same manner as before.

Phloridzin is said to possess the anti-intermittent property in a high degree, and to have proved successful where quinia had failed. It was employed by Dr. Konink in the dose of 10 or 16 grains, and effected cures in several cases of intermittent fever. Dr. De Ricci recommends it very strongly as a tonic in the dyspepsia of delicate females, in the debility of children requiring a supporting treatment, and in all cases in which quinia is indicated but is not well borne. He has never known it to disagree with patients in the dose of 10 grains three or four times a day. As a tonic, 5 grains of it may be given at a dose. Though nearly insoluble in water alone, it may be readily exhibited in solution by adding to the water a few drops of spirit of ammonia. (Dub. Quart. Journ., Aug. 1862.)

PHOSPHATE OF POTASSA. Potassa Phosphas. The phosphate of potassa, which has of late come into use as a medicine, is the neutral tribasic phosphate, having the formula $2KOH,PO_{4}$, and, therefore, a composition precisely analogous to that of the medicinal phosphates of soda and ammonia. It is derived from the variety of phosphoric acid containing three eqs. of water, by the substitution of two eqs. of potassa for two of water, and, notwithstanding its slight alkaline reaction, is called neutral, in order to distinguish it from the decidedly alkaline tribasic phosphate, $5KOH,PO_{4}$. It may be prepared precisely as phosphate of soda is prepared on page (1838); by fusing, fusing, by means of carbonic acid from carbonic acid, glacial acetic acid, $HOOH$, or with solution in water and efful- lution into aqueous phosphoric acid ($3HPO_{4}$). The medicinal phosphate of potassa is a white, amorphous, deliquescent salt, incapable of crystallization. It has been given as an alternative in scarlet fever and phthisis, and in some other diseases, with supposed advantage. The dose is from ten to thirty grains three times a day, dissolved in a teaspoonful of water.

PHOSPHATE OF ZINC. Zinci Phosphas. Dr. Barnes, of London, has brought forward this salt of zinc, as having special advantages over other salts of the same metal in the treatment of nervous diseases. The theoretical ground of preference is that, in diseases of the brain there is apt to be a waste of phosphorus in the cerebral substance, and the phosphate of zinc offers the means of supplying the deficiency. Phosphorus of zinc may be prepared by the neutralisation of sulphate of zinc and an alkaline phosphate. It is white, insoluble in water, but soluble in an excess of phosphoric acid. Dr. Barnes has found it peculiarly useful in the insanity occurring in the convalescence from fevers, in which it associates with quinia, and in epilepsy attended with disorder of the uterine functions. He also uses it preferably to the sulphate of zinc in the sweats of phthisis. He finds it less liable to disturb the stomach than the sulphate. It may be given in pill, or dissolved in water acidulated with phosphoric acid, in the dose of from one to three grains.

PHYSALIS ALKEKENGII. Alkekengi. Common Winter Cherry. A perennial herbaceous plant, growing wild in the south of Europe, and cultivated in our gardens. The fruit is a round red berry, about as large as a cherry, enclosed in the calyx, and containing numerous flat kidney-shaped seeds. All parts of the plant are bitter, specially the leaves and the capsules enveloping the fruit. The berries are very juicy, and have an acidulous, bitterish taste. By drying they shrink, and become of a brownish-red colour. The bitter principle has been isolated by MM. Desessnues and Chautard, and named by them physalin.
Pichurim Beans.—Pimpinella Saxifraga.

PART III.

It is obtained by agitating an infusion of the plant with chloroform, which extracts the bitter principle, and yields it by evaporation. To purify it, dissolve it in hot alcohol, add a little animal charcoal, filter, precipitate by water, and wash the precipitate with the same liquid. It is a light powder, white with a shade of yellow, of a taste slight at first, but in the end permanently bitter, very slightly soluble in cold water, somewhat more soluble in boiling water, and very soluble in alcohol and chloroform, especially with the aid of heat. It consists of carbon, hydrogen, and oxygen. (Journ. de Pharm., 3e sér., xxi. 24.) The berries are said to be aperient and diuretic, and have been recommended in suppression of urine, gravel, and other complaints of the urinary passages. M. Gendron recommends them very highly as a febrifuge. He thinks they are most effective when allowed to ripen and begin to dry on the stem. He usually administers about three draams daily in two doses. (Arch. Gén., xxiii. 536.) A French physician has lately published a pamphlet on gout, in which he strongly recommends alkekengi as more efficacious even than colchicum. He takes the flowers and unripe fruit, dries and powders them, makes the powder into a paste with water and a little slaked lime, treats the mixture with boiling alcohol, and finally filters and evaporates the alcoholic liquid. The residue is given in the form of pill, made with solution of silicate of soda and powdered Teucrium Chamomile. Five or six of the pills are taken daily. (Braithwaite's Retrospect, Am. ed., No. 46, p. 214.) From six to twelve berries, or an ounce of the expressed juice, may be taken for a dose; and much larger quantities are not injurious. They are consumed to a considerable extent in some parts of Europe as food. The berries of the Physalis viscosa, of this country, are said by Clayton to be remarkably diuretic.

W. PICHURIM BEANS. The seeds of an uncertain tree growing in Brazil, Guiana, Venezuela, and other parts of South America. The tree has been supposed to be the Ocotea Pichurim of Kunth (Laurus Pichurim, Richard, Aydemond Laurei, Nees); but its position in either of these genera is denied by F. Nees von Esenbeck; and the plant is now referred to the genus Nectandra with the specific name Puchury. There appear to be two varieties of Nectandra Puchury, one bearing larger and the other smaller fruit, and distinguished as the major and minor. Professor Carson, of the University of Pennsylvania, has had specimens of the fruit and other parts of the tree sent him, sufficient to verify the ascription of the Pichurim beans to this source. (Am. Journ. of Pharm., xxvii. 385.) The beans are the kernels of the fruit separated into halves. They are ovate-elongated or elliptical, flat on one side, convex on the other, of a grayish-brown colour externally, chocolate-coloured within, of an aromatic odour between that of nutmegs and sassafras, and of a spicy pungent taste. There are two kinds, one about an inch and a half long by half an inch in breadth, the other little more than half as large, rounder, and of a dark-brown colour. The former are said by Dr. Carson to come from Brazil, the latter from Venezuela, and may be severally the product of the varieties of the tree above referred to. (Ibid., p. 387.) Bonastre has found them to contain a concrete volatile oil, a fatty matter of the consistency of butter, stearin, resin, brown colouring matter, feacula, gum, sugar, and lignin. Their virtues depend on the volatile oil. In the American Journal of Pharmacy for Jan. 1851 (p. 1), Prof. Procter describes a liquid product brought from South America, known as "the native oil of laurel or sassafras," or "alceyo de sassoafra," said to be obtained by making incisions in the trunk of a tree growing on the Orinoco. As described by Prof. Procter, it is an oleo-resin, of the sp. gr. 0.938, of a light suburn colour, a peculiar penetrating odour, and an aromatic, bitterish, pungent, and somewhat camphoraceous taste. On distillation, almost the whole passes over in the shape of a colourless volatile oil; a small proportion only of resinous matter being left behind. This oleo-resin is conjectured to be the same as that employed for adulterating the copaiba exported from Maracaibo. It may be distinguished from copaiba by its ready solubility in alcohol of 0.938, and by the fact that its volatile oil is acted on by potassium. It is believed to be the same product as the "native oil of laurel" described by Pereira, which was obtained from Durecara, and by incisions in a large tree. Prof. Carson, on comparing with this a specimen of oil presented to him as obtained from the same tree with the fruit above mentioned, has no hesitation in considering them as identical, and, therefore, in referring the so-called native oil of laurel to Nectandra Puchury. In medical properties the pichurim beans resemble the common aromatics, and may be employed for the same purposes. In South America they are said to be used as a substitute for nutmeg, and have even been called by that name. They are rare in this country. The oil obtained from the tree is said to impart its odour to the perspiration and urine, and to be useful in rheumatism, gout, &c. The bark is sometimes employed as a tonic and febrifuge.

W. PIMPINELLA SAXIFRAGA. Small Burnet Saxifrage. Saxifraga. A perennial umbelliferous European plant, growing on sunny hills, and in dry meadows and pastures. The root is official in some parts of Europe. It has a strong, aromatic, yet unpleasant odour, and a sweetish, pungent, biting, aromatic, bitterish taste. Its active constituents are volatile oil and an acrid resin. It is considered diaphoretic, diuretic, and stomachic; and has been used in chronic catarrh, asthma, dropsy, amenorrhoea, &c. The dose in substance is about
half a drachm, and in infusion two drachms. The root is used also as a masticatory in toothache, as a gargle in palsy of the tongue and in collections of viscid mucus in the throat, and externally to remove freckles.

PINEKNeya PUBENS. Michaux. A large shrub or small tree, growing in South Carolina, Georgia, and Florida, in low and moist places along the sea-coast. It is closely allied, in botanical characters, to the Cinchonae, with which it was formerly ranked by some botanists. The bark is bitter, and has been used with advantage in intermittent fever. Dr. Law, of Georgia, cured six out of seven cases in which he administered it. The dose and mode of preparation are the same with those of cinchona. The chemical composition and medical properties of this bark deserve a fuller investigation than they have yet received.

PISCIDIA ERYTHRINA. Jamaica Dogwood. Dr. William Hamilton, of Plymouth, England, in a communication to the Pharmaceutical Journal (iv. 76, August, 1844), speaks of this plant as a powerful narcotic, capable of producing sleep and relieving pain in an extraordinary manner. He had noticed, when resident in the West Indies, the use of the bark of the root in the taking of fish, upon which, even when of a large size, it exercised a very strong narcotic effect. He was induced to try it as an anodyne in toothache, and found a saturated tincture exceedingly efficacious, not only affording relief when taken internally, but uniformly curing the pain when introduced upon a dose of cotton into the curious tooth. The bark of the root, to be effectual, should be gathered during the period of inflorescence in April. When chewed it has an unpleasant acridity like that of mezeereon. It yields its virtues to alcohol, but not to water. The formula employed by him in preparing the tincture was to macerate an ounce of the bark, in coarse powder, in four fluidounces of rectified spirit, for twenty-four hours, and then to filter. The dose is a fluidrachm. He first tried it on himself, when labouring under severe toothache, taking the quantity mentioned in cold water on going to bed. He first felt a violent sensation of heat internally, which gradually extended to the surface, and was followed by profuse perspiration, with profound sleep for twelve hours. On awaking, he was quite free from pain, and without the unpleasant sensations which follow a dose of opium.

PLANTAGO MAJOR. Plantain. A well-known perennial herb, growing in fields, by the roadsides, and in grass-plots, and abounding both in Europe and in this country. The leaves are saline, bitterish, and astringe to the taste; the root saline and sweetish. The plant has been considered refrigerant, diuretic, deobstruent, and somewhat astringent. The ancients esteemed it highly, and employed it in visceral obstructions, hemorrhages, particularly from the lungs, consumption, dysentery, and other complaints. In modern times it has been applied to similar purposes, and the root is said to have proved useful in intermittent fevers. At present, however, it is generally believed to be very feeble, and is little used internally. As an external application it has been recommended in ulcers of various kinds, and in indolent scrofulous tumours. Among the vulgar it is still much used as a vulnerary and as a dressing for blisters and sores. The dose of the expressed juice is from one to four fluidounces. Two ounces of the fresh root or leaves may be boiled in a pint of water, and given during the day. Externally the leaves are applied whole, or in decoction Plantago media and P. lanceolata or rib-grass, which are also indigenous, possess properties similar to those of P. Major, and may be used for the same purposes.

Under the name of semen psylliti, the seeds of several species of Plantago, growing in Europe, are sometimes kept in the shops. The best are those of Plantago Psyllium or flaveolata, which grows in the south of Europe and Barbary. They are small, about a line long by half a line in breadth, convex on one side, concave on the other, fleck-coloured, shining, inodorous, and nearly tasteless, but mucilaginous when chewed. They are demulcent and emollient, and may be used internally and externally in the same manner as flaxseed, which they closely resemble in medical properties.

PLATINUM. In 1826 Prof. Gmelin, of Tubingen, made experiments to determine the action of this metal on the economy. In 1841 Dr. Ferdinand Hoefrer published some observations on the same subject. The latter experimented chiefly with the bichloride, and the double chloride of platinum and sodium. They are both poisonous: the bichloride in the dose of 15 grains, the double chloride in that of 30 grains. When a concentrated solution of the bichloride is applied to the skin, it produces violent itching, followed by an eruption. Administered internally it irritates the mucous membrane of the stomach and occasions headache. The double chloride has no action when externally applied, and, when given internally, operates on the system in a less sensible manner than the bichloride. It possesses the power of augmenting the urine. Dr. Hoefrer ranks the preparations of platinum with the alteratives, by the side of those of iodine, arsenic, and gold. He considers them particularly suited to the treatment of syphilitic diseases; the bichloride to cases of long standing and inveterate, the double chloride to those which are recent. The dose of the bichloride is from half a grain to two grains twice a day, given in pill. Eight grains may be made into sixteen pill's, with a drachm of the extract of guaiacum wood of the French Code, and sufficient
PLUMBAGO. B. 1586

PLUMBAGO Europæa.—Populus. PART III.

Plumbago root. Of these, one, two, or three may be taken morning and evening. The double chloride may be prepared by dissolving five grains of the bichloride and eight of pure chloride of sodium in seven fluidounces of gum-water; and the whole may be taken by tablespoonfuls in the course of twenty-four hours. For frictions on indolent ulcers, Dr. Hoefer used an ointment composed of sixteen grains of the bichloride, thirty-two grains of extract of belladonna, and an ounce of lard. (Journ. de Pharm., xxvii. 213.) B.

PLUMBAGO Europæa. Leadwort. Dentellaria. A perennial, herbaceous plant, growing in the south of Europe. It has an acid taste, and, when chewed, excites a flow of saliva. This is particularly the case with the root, which has been long used to relieve toothache. Hence the plant derived the name of dentelaire, by which it is known in France. A decoction of the root in olive oil has been highly recommended for the cure of the itch. Writers differ much in their statements in relation to the activity of the plant, some speaking of it as a rubefacient, vesicatory, and caustic, and, when swallowed, as violently emetic, and liable to produce dangerous irritation of the alimentary canal; while others consider it nearly inert. Perhaps the difference may be ascribed in part to the use of the plant in the recent state in one case, and dried or long kept in the other. A crystallizable, acrid principle, called plumbacin, has been extracted from the root by Dulong.

POLYPODIUM VULGARE. Common Polypody. A fern belonging both to the old and new continents, and growing in the clefts of old walls, rocks, and decayed trunks of trees. The root, which is the part considered medicinal, is rather long, about as thick as a goose-quill, somewhat contorted, covered with brown, easily separable scales, furnished with slender radicles, and marked by numerous small tubercles. As found in the shops, it is sometimes destitute of the scales and radicles. Its colour is reddish-brown with a tinge of yellow, its odour disagreeably oleaginous, its taste peculiar, sweetish, somewhat bitter, and nauseous. The root of the variety growing upon the oak has been preferred, though without good reason. It was deemed purgative by the ancients, who employed it for the evacuation of bile and pituitous humours in melancholic and maniacal cases. Modern physicians have used it in similar complaints, and as a pectoral in chronic catarrh and asthma. At present, however, it is scarcely ever employed, being considered nearly inert. It was given in doses varying from a drachm to an ounce, usually in connection with cathartics.

POLYTRICHUM JUNIPERINUM. Hair-cap Moss. Robin's Rye. This moss is a native of the United States, and abounds in New England. For a particular description of it, the reader is referred to a communication in the Am. Journ. of Med. Sci., N. S. (xxvii. 267), by Dr. Wm. Wood, of East Windsor Hill, Connecticut, who speaks in very strong terms of its efficacy as a diuretic, having found it the most successful remedy which he has employed in the treatment of dropsy. He infuses a large handful of the whole plant in water, and allows the patient to drink freely of the tea, "the more so the better." Dr. Ariel Hunter, of Hyde Park, Vermont, has subsequently given additional testimony in its favour as a diuretic, doing good service in dysuria. (N. J. Med. and Surg. Reporter, ix. 417.) W.

POPULUS. Poplar. Several trees belonging to this genus have attracted some attention in a medical point of view. In most of them the leaf-buds are covered with a resinous exudation, which has a peculiar, agreeable, balsamic odour, and a bitterish, balsamic, somewhat pungent taste. This is abundant in the buds of Populus nigra or the black poplar of Europe, which are official in some parts of that continent. They contain resin and a peculiar volatile oil. The buds of P. balsamifera, growing in the northern parts of N. America and Siberia, are also highly balsamic; and a resin is said to be furnished by the tree, which is sometimes, though erroneously, called tacamahac. The virtues of the poplar buds are probably analogous to those of the turpentine and balsams. They have been used in pectoral, nephritic, and rheumatic complaints, in the form of tincture; and a liniment, made by macerating them in oil, has been applied externally in local rheumatism. The unguentum populeum of European pharmacy is made, according to the directions of the French Codex of 1837, by bruising in a marble mortar, and boiling in 2000 parts of lard, with a gentle fire, till the moisture is dissipated, 250 parts, each, of the fresh leaves of the black poppy, deadly nightshade, henbane, and black nightshade; then adding of the dried buds of the black poplar, bruised, 375 parts; digesting for 24 hours; straining with strong expression; and finally allowing the ointment to cool after defection. This is an anodyne ointment, occasionally employed in Europe in painful local affections. It has been ascertained that poplar buds are capable of imparting a principle to ointments, which in a considerable degree obviates their tendency to rancidity. The bark of certain species of poplar is possessed of tonic properties, and has been used in intermittent fever with advantage. Such is the case with that of P. tremuloides or American aspen, and of P. tremula or European aspen. In the bark of the latter Bracoonnot found salicin, and another crystallizable principle which he named populin. It is in these, probably, that the febrifuge properties of the bark reside. They may be obtained by precipitating a saturated decoction of the bark with solution of subacetate of lead, filtering, precipitating the excess of lead by sulphuric acid, again filtering, evaporating, adding animal
PART III.  
Portulaca Oleracea.—Prenanthes Serpentina.  

1587

charcoal towards the end of the evaporation, and filtering the liquor while hot. Salicin gradually separates, upon the cooling of the liquor, in the form of crystals. If, when this principle has ceased to crystallize, the excess of sulphuric acid in the liquid be saturated by a concentrated solution of carbonate of potassa, the populin will be precipitated. If this be pressed between folds of blotting paper, and redissolved in boiling water, it will be denoted, upon the cooling of the liquid, in the crystalline state. The leaves also of P. tremula afford populin, and more largely even than the bark. It is probable that both principles exist in the bark of P. tremuloides, and other species. Salicin is described under Salix. Populin is very light, purely white, and of a bitter, sweetish taste, analogous to that of liquorice. When heated it melts into a colourless and transparent liquid. It is soluble in 2000 parts of cold, and about 70 parts of boiling water; and is more soluble in boiling alcohol. Acetic acid and the diluted mineral acids dissolve it, and, upon the addition of an alkali, let it fall unchanged. Piria regards it as a complex body, consisting of benzoic acid, saligenin, and glucose. (See Am. Journ. of Pharm., xxiv. 240.) Of these principles saligenin and glucose have been found in salicin; and it was inferred that, by separating benzoic acid, populin might be converted into salicin. This has been effected by Piria. When populin is boiled with baryta water or milk of lime, the benzoic acid precipitated by sesquichloride of iron, the excess of iron removed by lime, and the excess of lime by carbonic acid, the remaining liquid yields salicin on evaporation. The same conversion may be effected by heating populin with an alcoholic solution of ammonia to 212°. Piria obtained from populin 28.9 per cent. of benzoic acid. (Pharm. Journ., xv. 378.) Dr. T. L. Phipson, basing his experiments upon the results of Piria, has succeeded in preparing populin artificially by combining salicin and benzoic acid. Nothing more is necessary than to dissolve the two substances in alcohol, and to concentrate the solution. Crystals are formed having all the characters of populin, and consisting of salicin and benzoic acid combined in the proportion of their equivalents. (Chem. News, Dec. 6, 1862, p. 278.)

PORTULACA OLERACEA. Garden Purslane. An annual succulent plant, growing in gardens and cultivated grounds, in the United States, Europe, and most other parts of the globe. It has an herbaceous, slightly saline taste, and is often used as greens, being boiled with meat, or other vegetables. It is considered a cooling diuretic, and is recommended in scurvy, and affections of the urinary passages. The seeds have been thought to be anthelmintic; but they are tasteless and inert.

POTENTILLA REPTANS. Cinquefoil. A perennial, creeping, European herb, with leaves which are usually quinate, and have thus given origin to the ordinary name of the plant. The root has a bitterish, stony, slightly sweetish taste, and was formerly used in diarrhoea, and other complaints for which astringents are usually prescribed.

POWDER OF ALGAROTH. Pulvis Algarothi. Oxychloride of Antimony, Nitroauriatic Oxide of Antimony. This powder is formed by dissolving tersulphuric acid of antimony in muriatic acid, assisting the action, at first, by a gentle heat, which must be gradually increased to ebullition; and then pouring the resulting solution, when cold, into a large quantity of water. By a double decomposition between the tersulphuric acid, and sulphuretted hydrogen is given off copiously by effervescence, and a solution of terchloride of antimony is formed. When this is thrown into water, the greater part of the terchloride is converted, by the elements of that liquid, into muriatic acid, which remains in solution, and teroxide of antimony, which precipitates in union with the remainder of the terchloride as the powder of Algaroth.

Properties, &c. This is a white powder, having a crystalline appearance if left long in contact with the solution from which it is precipitated. When exposed to a red heat it fuses, and forms a yellow liquid, which, on cooling, concretes into a greyish crystalline mass of a pearly aspect. Its usual composition is represented by the formula 2SbO3SbCl3-IIO. It was formerly used in the preparation of tartar emetic, but has been superseded for this purpose by the pure teroxide. It has also been used in medicine; but, owing to its unequal operation, has been properly laid aside. It is liable to contain tersulphuret of arsenic (orpiment), unless when obtained from the distilled concrete terchloride of antimony. (Laroche, Journ. de Pharm., March, 1849.)

PREANETHES SERPENTARIA. Lion’s Foot. This is a perennial indigenous herb, growing in the mountainous district of Virginia and North Carolina. It belongs to Synonemia Equitata in the sexual system, and to the natural family of Chicouraceae. The genus is characterized by its “four-flowered nodding heads, its cylindrical involucres calyculate at the base, its subtetebe unkeeved akenes, its scabrous pappus in several series, and its naked receptacles.” This particular species has rough dentate leaves, of which the radical are palmate, the cauline with long footstalks, sinuate pinnatifid, disposed to be three-lobed, with the middle lobe three-parted, the upper lanceolate. The racemes are terminal, somewhat panicled, short, and nodding, with an eight-eleft calyx, and twelve florets. (Pursh.) Dr. Darlington considers this a variety of Prenanthes alba. It is about two feet high, with purple flowers. Pursh speaks of it as in great repute among the inhabitants of the re-
Propylamia. PART III.

Propylamia. Propylamin. Secalina. Secalin. Under the head of Ergota (page 368) allusion has been already made to a volatile alkaloid discovered by Winckler in the ergot of rye, and therefore denominated by him secalin. This has since been identified with propylamia previously discovered in herring pickle; a fact which explains the fishy odour long known as one of the characteristics of ergot. The same alkaloid has been obtained as an artificial product from narcotina (see page 619), codein, cod-liver oil, and other substances, and has been found in saline combination in the flowers of Cretagus oxycantha, Sorbus aucuparia, and one or more species of Chenopodium. The mode of obtaining it from ergot has been described in Part I. (page 368). The following method of procuring it from herring pickle has been published by Prof. Procter in the American Journal of Pharmacy (March, 1859, p. 127). Herring pickle procured from the dealers in salt fish, having been mixed with sufficient potassa to render the liquid strongly alkaline, is introduced into a retort or alembic, and heated. The vapours are condensed in a receiver containing distilled water duly refrigerated, and the heat is continued until the distillate, as it forms, ceases to have the odour of herrings. The condensed liquid, which contains the propylamia separated by the potassa from its saline combination in the pickle, is now neutralized with muriatic acid, and carefully evaporated to dryness. Ammonia, which comes over and is condensed with the propylamia, combines like it with the muriatic acid, and the dry salt obtained is a mixture of the muriates of both these bases. This is exhausted with absolute alcohol, which dissolves the muriate of propylamia, and leaves the muriate of ammonia. If the alcoholic solution be treated with hydrate of lime, propylamia in vapour is given out abundantly with very little heat, and may be condensed in a receiver, which should be kept well cooled. The process may be simplified, as suggested by Prof. Procter in a subsequent number of the journal (May, 1859, p. 222), by acidulating the liquid in the receiver with muriatic acid, added gradually as the acid becomes neutralized, thus directly forming the muriate, which may be obtained crystallized by subsequent concentration, and, if necessary, freed from the accompanying muriate of ammonia in the manner already mentioned. In consequence of the volatility of propylamia, it is better kept in the state of the muriate; and this may either be used by the physician, or extemporaneously converted into propylamia, should it be wanted, by adding an equivalent of solution of potassa. The pure muriate may be obtained by the concentration of the alcoholic solution, formed as one of the steps of the preceding process. Propylamia is a colourless transparent liquid, of a characteristic odour, usually attended with some pungency, which may possibly be ascribed to the ammonia frequently mixed with it. It is soluble in water and alcohol, has a strong alkaline reaction, and forms crystallizable salts with the acids. If the end of a glass rod, previously dipped into muriatic acid, be held over the open mouth of a vial containing it, a white cloud of the muriate will be seen as in the case of ammonia. Though most of the salts of propylamia are soluble in water and alcohol, the sulphate is wholly insoluble in the latter of these menstrua. (Winckler.) Propylamia consists of carbon, hydrogen, and nitrogen; and its formula is C₂H₆N₂, which is represented by one eq. of propylene and one of ammonia C₄H₆N₂, or one of propyl and one of amidogen NH₂Cl₂.

Dr. Avenarius of St. Petersburg, Russia, first called attention to the use of propylamia in rheumatism, for which he considered it as a specific; so much so that a case of doubtful rheumatism might be diagnosed by the successful use of this remedy in the course of a few days. Between March, 1854, and June, 1856, he treated in the Hospital Kalinkin, in St. Petersburg, 250 cases of rheumatism with success. Some of the cases were acute, some chronic, many metastatic, with pericardial, pleuritic, and meningial complications; and hemiplegic and paraplegic cases were not wanting; but all recovered. In the acute cases the pain and fever disappeared in a day or two. He mixed 25 drops of propylamia with six fluidounces of distilled water, flavoured if necessary with sugar and oil of peppermint, and gave a tablespoonful every two or three hours, taking care that the alkaloid was pure and freshly prepared. (Ann. de Thérap., 1859, p. 74.) Confirmatory statements from various sources have since been published; and the remedy has been found serviceable in other painful affections. Dr. B. F. Eaton, of Barnet, Vermont, has given in the Boston Medical and Surgical Journal an account of a severe case of neuralgia of the face, in which the pain appeared to have been entirely subdued by it in less than 24 hours. After using it for about three days, the patient was seized with vomiting, accompanied with faintness, and excessive thirst; but whether these phenomena were the effects of the propylamia could not be determined. (See Am. Journ. of Pharm., May, 1862, p. 277) Experiments are wanting to show the precise physiological properties of this alkaloid; and soon or
in what manner it may prove deleterious in overdoses. There is probably no better plan of administering the remedy than that recommended by Dr. Avenarius; namely in watery solution. A solution of 24 drops in six fluidounces of peppermint water, with two drachmas of sugar, may be given in the dose of half a fluidounce, equivalent to two drops of the alkaloid, every two hours in the more acute cases. Or 36 grains of the muriate may be substituted in the mixture for the 24 drops of the alkaloid, and 6 fluidrachms of the solution of potassa added. This would give, with each dose of the propylamine, three or four grains of chloride of potassium, which could have no material effect, and certainly none of an injurious character.

PRUNELLA VULGARIS. Self-heal. Heat-all. A small perennial labiate plant, common both in Europe and the United States, growing especially by the waysides. It is inodorous, but has an austere bitterish taste. The herb in flower was formerly used, in the state of infusion or decoction, in hemorrhages and diarrhoea, and as a gargle in sorethroat. In this country it is not employed in regular practice.

PULMONARIA OFFICINALLIS. Lungwort. An herbaceous perennial, European plant, sometimes cultivated in this country in gardens. The leaves are inodorous, and have an herbaceous, somewhat mucilaginous, and feebly astringent taste. They have been considered pectoral and demulcent, and employed in catarrh, haemoptysis, consumption, and other affections of the chest; but their virtues are doubtful, and they were probably used in pectoral complaints as much on account of the supposed resemblance of their speckled surface to that of the lungs, as from the possession of any positively useful properties.

PUMICE STONE. Pumex. A very light porous stone, found in the vicinity of active and extinct volcanoes, and believed to have been thrown up during their eruption. The pumice stone of commerce is said to be obtained chiefly from Lipari. It is used whole, in the manner of a file, for removing the outer surfaces of bodies, or for rubbing down inequalities, and, in the state of powder, for polishing glass, metals, stones, &c.; purposes to which it is adapted by the hardness of its particles.

PYRETHRUM PARTHENIUM. (Wild.) Matricaria Parthenium. (Linn.) Chrysanthemum Parthenium. (Persoon.) Feverfew. A perennial herbaceous plant, about two feet high, with an erect, branching stem, pinnate leaves, oblong, obtuse, gashed, and dentate leaflets, and compound flowers in a corymb upon branching peduncles. It is a native of Europe, but cultivated in our gardens. The whole herbaceous part is used. The plant has an odour and taste analogous to those of chamomile, which it resembles also in the appearance of its flowers, and in its medical virtues. According to Zeller, a pound of it yields 4-8 grains of volatile oil. (Cent. Blatt, 1855, p. 205.) Though little employed, it is undoubtedly possessed of useful tonic properties. The flowers of this and of a closely resembling species, Matricaria parthenioides (Desf.), are said to be used in France, to a considerable extent, indiscriminately with those of the true chamomile plant, Anthemis nobilis, which they closely resemble, especially when double. They may, however, be distinguished, in this state, by their peculiar odour, their smaller receptacle, which is, moreover, rounded and flattened above, instead of being conical and somewhat pointed as in the Anthemis, and by the tubular five-toothed central florets, which in the chamomile are small, few, and scarcely visible, but, in the two species of Parthenium, are large, very numerous, and very long. Two other species of Parthenium, P. roseum and P. carneum, have recently come into notice, as the source of the Persian insect powder. (See Insect Powder, page 1537.)

PYROACETIC SPIRIT. Pyroacetic Ether. Acetone. This substance may be obtained by carefully distilling acetate of lime, and rectifying the product by repeated distillations from quicklime in a water-bath, until the boiling point becomes stationary, whereby it is freed from water and empyreumatic oil. It is a colourless, volatile, inflammable liquid, having a peculiar penetrating smell, and a pungent taste like that of peppermint. Its specific gravity is 0-792, and boiling point 132°. As found in the shops its density is not generally lower than 0-820. It is miscible in all proportions with water, ether, and alcohol, without disturbing its transparency. If it becomes turbid when mixed with water, the fact shows that it contains empyreumatic oil. It has been confounded with pyroxylic spirit, from which it is distinguished by its inability to dissolve a saturated solution of chloride of calcium, which is instantly dissolved in pyroxylic spirit. (Santaen.) Its formula is C₆H₄O₂; while that of pyroxylic spirit is C₅H₆O₂. In constitution it bears considerable resemblance to alcohol. Thus, its formula doubled is C₁₂H₈O₄, and that of alcohol is C₁₀H₈O₄. It was thought at one time that the substance brought to the notice of the profession by Dr. John Hastings, of London, under the name of naphtha, as a remedy for pulmonary consumption, was pyroacetic spirit; but it now appears to be settled that what he intended was pyroxylic spirit. (See Spiritus Pyroxylicus Rectificatus, page 808.) There is no doubt that these spirits were used indiscriminately in the therapeutic trials which grew out of the publication of Dr. Hastings' book; but no exact experiments have been made, so far as we know, to determine the precise physiological action of pyroacetic spirit.
Pyrogallic Acid.—Rennet.  

Pyrogallic Acid. Pyrogalline or Galline (Rosing). This substance has recently acquired some importance as an agent in photography. It is one of the results of the igneous decomposition of gallic acid, and may be obtained by submitting extract of galls to the same treatment as that used for preparing benzoic acid from benzoin. The vapours of pyrogallic acid rise, and condense on the upper surface of the paper diaphragm. The chief difficulty in the process is properly to regulate the heat; as at a high temperature this acid passes rapidly into metagallic acid, and thus the product is diminished. According to Löwig, it is best prepared by heating gallic acid, previously dried at 212° F., in a glass retort, by means of a chloride of zinc bath, to 410° F., when the pure acid sublimes. Liebig recommends another method, calculated especially to obviate the effects of heat, which, with all the details, may be seen in the Am. Journ. of Pharm. for July, 1857 (p. 388). In the same journal (July, 1854, p. 302) are the details of a process by H. Gruneberg, of the character of the one first referred to above, by which he obtained from 50 pounds of Chinese galls 2 pounds of the acid.

Pyrogallic acid is in white, shining scales, inodorous, very bitter, soluble in three and a half parts of water, readily dissolved by alcohol and ether, fusible at 239° F., and sublimable at 410° in irritating vapours. According to Rosing, of Christiania, it is always partially converted, when sublimed, into metagallic acid, to which probably it owes its acid reaction as generally found in commerce; for, when quite pure, it has no influence on litmus paper. Rosing denied altogether its claims to be considered as an acid, and proposed to add pyrogalline or galline. (Journ. de Pharm., Juillet, 1857, p. 53.) In a subsequent memoir, however, he admits its neutralizing power, and gives as its formula C₇H₇O₇. One of its characteristic properties is its strong affinity for oxygen, in consequence of which it instantly undergoes change by contact with chlorine, iodine, bromine, and the acids which readily yield oxygen. Through the same property it rapidly reduces some of the metallic oxides; and its use in photography is based on this effect exercised on the salts of silver. Though unalterable in the air when quite dry, it is rapidly changed in solution by the absorption of oxygen, so that it may be used for ascertaining the proportion of this gas in a mixture of gases. W.

Realgar. This is the bisulphuratic of arsenic, consisting of one eq. of arsenic 75, and two of sulphur 32 = 107. It is found native in Saxony, Bohemia, Transylvania, and in various volcanic regions. Realgar is artificially made by mixing arsenious red with about half its weight of sulphur. (Turner.) Thus prepared, it is of a dull yellowish, transparent, of a beautiful ruby-red colour, of a uniform conchoidal fracture, somewhat transparent in thin layers, and capable of being sublimed without change. Native realgar is said to be innocent when taken internally, while that artificially prepared is poisonous, in consequence, according to Guibourt, of containing a little arsenious acid. Realgar is used only as a pigment. W.

Red Chalk. Redder. A mineral substance of a deep red colour, of a compact texture, dry to the touch, adhering to the tongue, about as hard as chalk, soiling the fingers when handled, and leaving a lively red trace when drawn over paper. It consists of clay and oxide of iron, and is intermediate between bole and red ochre, containing more oxide of iron than the former, and less than the latter. It is used for drawing lines upon wood, &c., and is also used to make crayons by levigating and moisturizing it, then forming it into a paste with mucilage of gum arabic, moulding this into cylinders, and drying it in the shade. It has been used internally as an absorbent and astringent. W.

Rennet. Gastric Juice. Pepsine. As a remedial agent, the gastric juice of the inferior animals has been used in three forms; 1. that of the fresh liquid taken from the stomach, 2. that of rennet, or an infusion of the dried stomach, in wine or water, and 3. that of a preparation called pepsine.

1. Gastric Juice is a liquid secretion of the mucous membrane of the stomach, whereby nitrogenous food is rendered soluble and capable of being absorbed, and other changes are effected essential to healthful digestion. Various methods have been employed for extracting it from the stomach for experiment, which it is unnecessary here to describe. For use in medicine, the most convenient method is to collect it from the stomachs of animals killed fasting, as the hog, sheep, and calf, and then deprive it, by filtration, of the mucous and undigestible alimentary matters mingled with it. In this state it is a limpid liquid, slightly yellowish or brownish-yellow, heavier than water, of a somewhat saltish taste, and a characteristic odour, which, when the juice is heated, resembles that of soup. It usually has an acid reaction. At the temperature of 100° or lower, it has the property of dissolving nitrogenous articles of food, and, without affecting starch, of changing glucose or the sugar of grapes into lactic acid. When separated from its attendant acid, it loses in a greater or less degree this solvent power, which it recovers upon the addition of lactic or muriatic acid. The idea has been advanced that, in normal digestion, it supplies itself with the requisite lactic acid, by converting into that substance the glucose taken into the stomach, or resulting from the reaction of saliva or the gastric mucus upon starch. But in cases where no starch is taken, there must be other means of supplying the neces-
PART III.

Rennet.

1591

Vary acid. When the juice is heated to the boiling point, it becomes turbid, and loses the solvent property. The same change takes place more slowly at the temperature of 122° F. Strong alcohol causes a deposition of solid matter, and impairs the digestive power. Tannin produces a precipitate which has no influence on food. Some of the metallic salts, as bichloride of mercury and acetate of lead, also produce a precipitate; but this, when deprived of the metallic oxide, regains the characteristic solvent property. Pure gastric juice contains about 97 per cent. of water, 1.75 of salts, a free acid, and 1.25 of a substance, which has been considered by some chemists as a distinct organic principle, and has received the name of peepin. (Boudault, Journ. de Pharm., Sept. 1856, p. 162.) This principle is nitrogenous, and is believed to have the properties of a ferment, whereby the gastric juice is enabled, with the assistance of an acid, to exercise its peculiar power over food. It may be separated from the gastric juice by first precipitating this with a metallic salt, as the acetate of lead, and then decomposing the metallic precipitate by sulphuretted hydrogen, which throws down the metal as a sulphuret, and leaves the peepin in solution. The liquid is then evaporated at a very gentle heat, and the peepin is left in the form of a soft, viscous substance, which can with difficulty be brought to a dry state without addition. But it is very doubtful whether the substance thus procured, though it has the digestive power of the gastric juice, is a pure proximate principle; as, in the purest state in which it has been obtained, it does not yield identical results on analysis. When gastric juice is completely protected from the air, it may be kept unchanged for a long time; but, on exposure, it speedily undergoes decomposition, acquires a very offensive odour, and loses its characteristic digestive property. The juice itself is almost never used internally; but, more than forty years ago, it was employed by Dr. P. S. Physick, the celebrated surgeon of Philadelphia, with considerable success, as a local application to cancers and sloughing ulcers, with the view of removing the dead bone and flesh, correcting the offensive odour, and yielding a healthful stimulus to the diseased surface. It has also been used with success, by Dr. Ellsworth, of Hartford, Connecticut, for dissolving a portion of tough animal food, which had become impacted in the esophagus of a lad affected with stricture of that passage. The gastric juice of a pig was used. (Boat. Med. and Surg. Journ., April 17, 1856.)

2. Rennet. This is an aqueous or vinous infusion of the dried stomach of the calf, though that of the sheep or other animal would probably answer the same purpose. It is much used, as every one knows, for curdling milk; a property which it owes to a portion of the gastric secretion, retained and dried in the mucous tissue of the stomach. To the same material it probably owes the property which it possesses of converting glucose into lactic acid; and there is little doubt that it is capable, in greater or less degree, of exercising the solvent property of gastric juice over albuminous and fibrinous food. The first of the properties just referred to suggested to Dr. James Gray, of Glasgow, the use of rennet in diabetes, with the object of promoting the conversion of any sugar of grapes that might be formed in the stomach into lactic acid, and thus preventing its entrance into the circulation in its unchanged state. He met with considerable success in this use of the remedy; and it has since been employed by others, in the same disease, with supposed advantage. Dr. Gray gave a teaspoonful of the rennet after each meal. To be efficient it must be recently prepared, and of such strength that a teaspoonful will coagulate a pint of milk in five minutes. (Ed. Monthly Journ. of Med. Sci., Jan. 1853, p. 51.) Rennet seems also to have been popularly employed for promoting defective digestion, in the west of England. (Med. Times and Gaz., April, 1857, p. 411.) It is highly probable that the preparation, usually employed to curdle milk, may contribute to the ready digestibility of the curds and whey, so favourite an article of diet among children in this country. Dr. Geo. Ellis gives the following method of preparing rennet-wine, from which he has obtained the most satisfactory results, when peepin from inadequate preparation had failed him. Take the stomach of a calf immediately after death, cut off and reject about three inches of the upper or cardiac portion, slit the stomach longitudinally, wipe it gently with a dry napkin so as to remove as little of the clean mucus as possible, then cut it into small pieces, the smaller the better, put it into a common wine bottle, fill the bottle with good sherry, and let it stand corked for three weeks. The dose is a teaspoonful, in a wineglassful of water, immediately after each meal. It is known to be good if a teaspoonful will coagulate half a pint of milk in two minutes at 100° F. (Dub. Med. Press, July 16, 1862.)

Pepine. Various attempts have been made to concentrate, and bring to a convenient form for administration, the peptic principle of the gastric juice. It must not be supposed that the substances prepared with this object, and sold under the name of pepine, have any claim to be considered as the pure principle, which, for the sake of distinction, may be called peepin. The one which approaches nearest that condition is the pepine prepared by M. Boudault. His process is as follows. The rennet bags of sheep, quite fresh, are opened, turned inside out, and washed by a gentle stream of water; the mucous membrane is then scraped off, bruised in a mortar so as to rupture the cells, and digested for twelve hours in pure water. The infusion thus obtained is precipitated by acetate of lead, and the pre-
Reseda Luteola.—Rhamnus Catharticus.

_ PART III. _

citrate, consisting of pepsin and oxide of lead, is mixed with water and decomposed by sulphuretted hydrogen, which throws down the lead, leaving the pepsin in solution. The liquid, having been filtered, is evaporated, at about 100 F., to a syrupy consistence; after which sufficient perfectly dry starch is added to absorb the semi-liquid matter, and bring it to the state of a dry powder. Lactic acid is sometimes added in small proportion to the liquid before evaporation, and no doubt contributes to its efficiency. An attempt to evaporate to dryness might injure the preparation; and at best a matter would be obtained; strongly disposed to absorb moisture, and consequently to undergo putrefaction. Starch is chosen for the solidification of the syrupy mass, on account of its absorbent property, and because it is not affected by the digestive power of the pepsin. If properly prepared, 15 grains of Boudault's pepsin, with the aid of a little lactic or muriatic acid if the former was not employed in the process, will cause the solution in water of four times its weight of fibrin at the temperature of the human body; and the amount of starch added in the process is proportioned to this result. (Pharm. Journ., xvi. 472.) Much care is requisite to use fresh rennet bags, before they have begun to undergo decomposition, and not to allow the temperature used in evaporation to exceed 100 F. It is asserted, of the pepsin of Boudault, that it has the reactions of the gastric juice above referred to, and is fully capable of replacing that liquid for the purposes of digestion. It may be given either with or without lactic or muriatic acid; the addition being unnecessary when there is already sufficient acid in the stomach. A spurious substance has been sold for it; but may be distinguished by the difference of its reactions, and agency in dissolving fibrin. The genuine pepsin, dissolved in water, is precipitated by acetate of lead, tannic acid, and strong alcohol; and 15 grains of it should, in 12 hours, effect the solution of a drachm and a half of boiled white of egg, or chopped meat, in half a fluidounce of water, at 100° F. (Ballard, Med. Times and Gaz., Feb. 1557, p. 177.) The spurious substance is destitute of these properties.

The idea of employing the gastric juice, or some representative of it, in order to promote digestion, is not new; and it would be difficult to determine to whom the original use of this remedy is to be ascribed. According to Boudault, however, the application of the principle pepsin to this purpose was first suggested by Dr. Corvisart, of Paris. (Journ. de Pharm., xxx. 149.) Boudault's preparation has been used in England by many practitioners with good effects, if we may judge from the reports made in the journals. The particular condition to which it is applicable is that debility of stomach, from whatever cause arising, in which gastric juice is not produced in sufficient quantity, or of sufficient power, to enable the requisite amount of food to be digested. In such cases, the debility of the stomach is kept up by the want of due nutrition of the organ, originating in its own defective function; and it has, therefore, no power of recovering its healthy condition. Artificial digestion supplies the deficient nutriment; and the stomach, being now duly nourished, resumes its proper function. Dyspepsia, the debility of stomach following chronic dysentery, and that attendant upon convalescence, and certain exhausting diseases, such as phthisis, afford suitable occasions for its use. It is thought to have proved useful in the vomiting of pregnancy. The dose of Boudault's preparation is 15 grains before each meal, to be taken in powder, or suspended in soup or syrup. Boudault recommends specially the syrup of cherries, as well calculated to cover its disagreeable taste. There is no incompatibility between it and other remedies usually employed in similar cases, such as the simple bitters, quinia, nux vomica, the chalybeates, and opiates.

RESEDA LUTEOLA. Weld. Dyers' Weed. An annual European plant, naturalized in the United States. It is inodorous, and has a bitter taste, which is very adhesive. Chevreul obtained from it by sublimation a peculiar yellow colouring matter, which he called _luteolin_. In medicine it has been employed as a diaphoretic and diuretic, but is now neglected. On the continent of Europe it is much employed for dyeing yellow, and, before the introduction of quercitron into England, was extensively applied to the same purpose in that country. The whole plant is used.

RHAMNUS CATHARTICUS. Buckthorn. The Edinburgh College recognised the berries of this plant, and the London, the juice of the fruit; but neither has been admitted into the U.S. Pharmacopoeia or into that of the British Council. The plant belongs to the Pentandra Monogynia of the Linnaean system, and to the natural family Rhamnaceae. The following is the essential generic character. _Colix tubular._ Corolla scales deferring the stamens, inserted into the calyx. _Berry._ (Weld.) The purging buckthorn is a shrub seven or eight feet high, with branches terminating in a sharp spine. The leaves are in fascicles, one short footstalk, ovate, serrate, veined. The flowers are usually dioecious, in clusters, small, greenish, pedunculate, with a four-cleft calyx, and four very small scale-like petals, placed in the male flower, behind the stamens, which equal them in number. The fruit is a four-seeded berry. The shrub is a native of Europe, and has been found growing wild in this country. It was first discovered in the Highlands of New York by Dr. Barratt. (Eaton's Manual.) It flowers in May and June, and ripens its fruit in the latter part of September. The berries and their juice are used. When ripe they are of the size of a pea,
Rhododendrum: 

Vogel obtained from the juice of the berries a peculiar colouring matter, acetic acid, mucilage, sugar, and a nitrogenous substance. Hubert found green colouring matter, acetic and malic acids, brown gummy matter, and a bitter substance which he considered as the purgative principle. M. Fleury obtained a peculiar crystallizable principle, which is contained both in the expressed juice and the residue remaining after expression, and for which he proposed the name of rhamnin; but he did not ascertain whether it possessed cathartic properties. (See Journ. de Pharm., xxvii. 606.) Winckler obtained from the ripe fruit a principle which he called catharin, and believes that the rhamnin of Fleury, which was obtained from the unripe berries, is converted into that principle and grape sugar as the fruit matures. (Chem. Guz., viii. 292.) The catharin of Winckler, which must not be confounded with the substance of the same name at one time supposed to be the purgative principle of senna, may be procured by evaporating the expressed juice of the berries to the consistency of syrup, treating this repeatedly with boiling absolute alcohol till it ceases to yield bitterness to the menstruum, mixing the tinctures, allowing the liquor to become cold, filtering, adding a large excess of ether, allowing the mixed liquids to stand, then filtering, evaporating in a water-bath, and repeating the process with the residue. The catharin thus obtained is a pale-yellow powder, very bitter, soluble in water and alcohol but not in ether, and actively cathartic in the dose of from one to three grains. (See N. Y. Journ. of Pharm., April, 1853, and Am. Journ. of Pharm., xxv. 520.)

Medical Properties and Uses. Both the berries and the expressed juice are actively purgative; but, as they are apt to occasion nausea and severe griping, with much thirst and dryness of the mouth and throat, they are now little employed. They formerly enjoyed considerable reputation as a hydragogue cathartic in dropsey; and were given also in rheumatism and gout. The only shape in which they are used in this country is that of syrup, which is sometimes, though rarely, added to hydragogue or diuretic mixtures. The syrup was formerly officinal, and was prepared by adding to a pint (Imp. meas.) of the juice, allowed to stand for three days, and then filtered, six drachms of sliced ginger, and six drachms of powdered pimento, macerating for four hours with a gentle heat and again straining; then boiling down three other pints of the juice, allowed to stand and filtered, of the dried a drachm, of the expressed juice a fluidounce, and of the syrup from four to eight fluid drachms. Under the name of cortex frangula, the bark of Rhamnus Frangula is used in Germany as a cathartic. Buchner found in this bark a peculiar yellow volatile colouring principle, which he called rhamnozanthin, and which may be obtained by subjecting the alcoholic and ethereal extract to distillation. (Journ. de Pharm., xxvi., xxv. 293.)

RHODODENDRUM CRYSANTHUM. Yellow-flowered Rhododendron. This is a beautiful evergreen shrub, about a foot high, with spreading branches, and oblong, obtuse, thick leaves, narrowed towards their footstalks, reflexed at the margin, much veined, rugged and deep-green upon their upper surface, ferruginous or glaucous beneath, and surrounding the branches upon strong petioles. The flowers are large, yellow, on long peduncles, and in terminal umbels. The corolla is wheel-shaped, with its border divided into five roundish, spreading segments. The plant is a native of Siberia, delighting in mountainous situations, and flowering in June and July. The leaves are the part used. When fresh, they have a feeble odour, said to resemble that of rhubarb. In the dried state, they are inodorous, but have an austere, astringent, bitterish taste. They yield their virtues to water and alcohol. They are stimulant, narcotic, and diaphoretic, producing, when first taken, increase of heat and arterial action, subsequently a diminished frequency of the pulse, and, in large doses, vomiting, purging, and delirium. They have been long employed in Siberia as a remedy in rheumatism; and their use has extended to various parts of Europe. Their action is said to be accompanied with a sensation of creeping or pricking in the affected part, which subsides in a few hours, leaving the part free from pain. They have been recommended also in gout, lues veneres, and palsy. In Siberia they are prepared by infusing two drachms of the dried leaves in about ten ounces of water, in a close vessel, and keeping the liquid near the boiling point during the night. The strained liquor is taken in the morning; and a repetition of the dose three or four days successively generally effects a cure. The remedy is not used in this country.

RIGA BALSAM. Balsamum Corpandum. Balsamum Libani. This is a product of Pinus Jembera, a large tree growing in the mountainous regions and northern latitudes of Europe.
Robinia Pseudo-acacia.—Salep.

Robinia. The juice exudes from the extremities of the young twigs, and is collected in flasks suspended from them. It is a thin, white fluid, having an odour analogous to that of juniper, and possessing the ordinary terebinthinate properties. In this country it is very rare; but it is occasionally brought from Riga or Cronstadt in bottles. A similar product, called Hungarian balsam, is obtained in the same manner from Pinus Pumilio, growing on the mountains of Switzerland, Austria, and Hungary. It is scarcely known in the United States.

ROBINIA PSEUDO-ACACIA. Locust Tree. This well-known indigenous tree, so much valued by the farmers for fence-posts in consequence of the great durability of its wood, and so much a favourite for the beauty of its foliage and the sweetness of its flowers, is also supposed by some to possess remedial properties, and has a place in the Materia Medica of the "eclectics." The bark of the root is the most active part, and is said to be tonic, and in large doses purgative and emetic. Three cases of poisoning in children, who had eaten of the root by mistake, have been recently recorded. The symptoms were like those produced by an overdose of belladonna; but all the children recovered. One of them, who happened to be labouring under intermittent fever at the time, had no return of the paroxysms afterwards. (Ann. de Thérap., 1860, p. 64.) These facts render caution advisable in the use of the root, yet are also well calculated to stimulate inquiry.

ROTTEN STONE. Terra Cariosa. An earthy mineral, occurring in light, dull, friable masses, dry to the touch, of a very fine grain, and of an ash-yellow colour. It is obtained from Derbyshire in England, and is used for polishing metals. A particular account of it may be found in the American Journal of Pharmacy (Sept. 1860, p. 463).

SAGAPENUM. Though one of the officinals of the late London Pharmacopoeia, Sagapenum has been omitted in the British. It belongs to the category of gum-resins. All that is known in relation to its source is, that it is the concrete juice of a plant, probably umbelliferous, growing in Persia. The plant is conjectured to be a species of Feresa, and Wildenow supposed it to be F. Persica, but without sufficient evidence. The drug is brought from Alexandria, Smyrna, and other parts of the Levant. It is in irregular masses, composed of agglutinated fragments, slightly translucent of a brownish-yellow, olive, or reddish-yellow colour externally, paler internally, brittle, of a consistence somewhat resembling that of wax, and often mixed with impurities, especially with seeds more or less entire. An inferior variety is soft, tough, and of uniform consistence. It has an alicious odour, less disagreeable than that of assafetida, and a hot, nauseous, bitterish taste. It softens and becomes tenacious by the heat of the hand. The effect of time and exposure is to harden and render it darker. It is inflammable, burning with a white flame and much smoke, and leaving a light spongy charcoal. Pure alcohol and water dissolve it partially, diluted alcohol almost entirely. Distilled with water it affords a small quantity of volatile oil; and the water is strongly impregnated with its flavour. According to Pelletier, it contains 54-26 per cent. of resin, 31-94 of gum, 1-0 of bassorin, 0-60 of a peculiar substance, 0-40 of acidalous malate of lime, and 11-80 of volatile oil including loss. Brands found 3-75 per cent of volatile oil. This is pale-yellow, very fluid, lighter than water, and of a disagreeable alicious odour.

Medical Properties and Uses. Sagapenum is a moderate stimulant, resembling assafetida, but much inferior, and usually considered as intermediate between that gum-resin and galbanum. It has been given as an emmenagogue and antispasmodic in amenorrhoea, hysteria, chlorosis, &c., but is now seldom used. It was known to the ancients; and Dioscorides speaks of it as being derived from Media. The dose is from ten to thirty grains, and may be given in pill or emulsion. Sagapenum is also considered discutient, and has been occasionally applied externally, in the form of plaster, to indolent tumours.

SALEP. Though not recognised either in the U. S. Pharmacopoeia or in the British, this substance deserves a brief notice, as it is frequently mentioned by writers on the materia medica, and is occasionally to be found in the shops. The name is given to the prepared bulbs of Orchis mascula and other species of the same genus. The male orchis is a native of Europe, the Levant, and northern Africa. Its bulbs, which are two in number, oval or roundish, internally white and spongy, are prepared by removing their epidermis, plunging them into boiling water, then straining them together, and drying them in the sun or by the fire. By this process they acquire the appearance and consistence which distinguish them as found in the shops. Landerer, however, denies that, as prepared in Greece or Macedonia, they are dipped in boiling water, and ascribes their horny character to their being quickly dried in a baking oven. (Pharm. Journ., March, 1850.) They were formerly procured exclusively from Macedonia, Asia Minor, and Persia, but are now said to be prepared in France, and perhaps other parts of Western Europe.

Salep is in small, oval, irregular masses, hard, horny, semi-transparent, of a yellowish colour, a feeble odour, and a mild mucilaginous taste. It is sometimes kept in the state of powder. In composition and relation to water it is closely analogous to tragacanth, consisting of a substance insoluble, but swelling up in cold water (bassorin), of another in much smaller proportion, soluble in cold water, and of minute quantities of saline matters.
PART III.

Sandalarach.—Saponaria Officinalis.

It also occasionally contains a little starch. It is highly nutritious, and may be employed for the same purposes as tapioca, sago, &c. The reputation which it enjoyed among the ancients, and still enjoys in the East, of possessing aphrodisiac properties, is wholly without foundation. On account of its hardness, salep, in its ordinary state, is of difficult pulverisation; but the difficulty is removed by macerating it in cold water until it becomes soft, and then rapidly drying it.

W.

SANDARACH. Sandaraca. This is a resinous substance obtained from Thuya articulata, an evergreen tree growing in the north of Africa. It is in small, irregular, roundish-oblong grains or tears, of a pale-yellow colour, sometimes inclining to brown, more or less transparent, dry and brittle, breaking into a powder under the teeth, of a faint agreeable odour increased by warmth, and of a resinous, slightly acrid taste. It melts with heat, diffusing a strong balsamic odour, and easily inflames. It is almost entirely soluble in ordinary alcohol, and entirely so in that liquid when anhydrous, and in ether. Heated oil of turpentine also dissolves the greater part of it, but very slowly. According to Unverdorben, it consists of three resins, varying in their relations to alcohol, ether, and oil of turpentine. The sandaracen of Geise, which remains after sandarach has been exposed to the action of ordinary alcohol, is a mixture of two of these resins. Sandarach was formerly given internally, and entered into the composition of various ointments and plasters. At present it is used chiefly as a varnish, and as incense; and its powder is rubbed upon paper to prevent ink from spreading, after letters have been scratched out.

W.

SANICULA MARILANDICA. Sanicle. An indigenous, umbelliferous, perennial, herbaceous plant, two or three feet in height, growing in woods and thickets, in almost all parts of the United States, as far south as South Carolina. For its botanical character, see Eaton’s Botany, and Torrey and Gray’s N. Am. Flora (vol. i. p. 601). The root is the part used, and is popularly known in some parts of the country by the name of black snakeroot. It is fibrous and of an aromatic taste, and has been used as a domestic remedy in intermittent fever. Dr. J. B. Zabriskie has found it highly effectual in chorea. He considers it most efficient in substance, and gives the powder to children of eight or ten years old in the dose of half a drachm three times a day. (Am. Journ. of Med. Sci., N. S., xii. 374.)

W.

SANTALUM ALBUM et CITRINUM. Sandal wood. Saunders. There are three kinds of wood known by the name of santalum or saunders:—1. santalum rubrum, or red saunders, from Pterocarpus santalinus, already described in this work (page 742) under the official name of Sintalum; 2. santalum album, or white saunders, from the Santalum album of Linneus, growing in the East Indies, the S. Pacific Islands, and South America; and 3. santalum citrinum, or yellow saunders, formerly supposed to be the inner wood of the tree of which the outer constituted white saunders, but now stated to be from a different tree, the S. freycinetianum of M. Gaudichaud, growing in the Sandwich Islands, the Fecjje Islands, the Marquesas, on the coast of Malabar, &c. It is the last-mentioned species which supplies the sandal wood so highly valued by the Chinese. Both kinds have a very agreeable aromatic odour. The white is thought by the East India physicians to be refreshing, and useful in remittent fevers, gonorrhœa, and other complaints. It was formerly used in European pharmacy, and still enters into certain compound syrups, confections, &c. The Chinese employ the yellow saunders chiefly as a perfume, burning it in their temples, sick chambers, &c., and obtain from it a volatile oil by distillation, which they mix with oil of roses. This variety was also formerly used in Europe, and praised as cordial and alexipharmic. The three saunders were not unfrequently combined in the same preparation. (Merat et De Leno.)

W.

SAPONARIA OFFICINALIS. Soapwort. A perennial, herbaceous plant, growing wild in this country in the vicinity of cultivation, but probably introduced from Europe. It is commonly known by the vulgar name of bouncing bet. It is one or two feet high, with smooth, lanceolate leaves, and clusters of conspicuous whitish or slightly purplish flowers, which appear in July and August. The root and leaves are employed. They are inodorous, and of a taste at first bitterish and slightly sweetish, afterwards somewhat pungent, continuing long, and leaving a slight sense of numbness on the tongue. They impart to water the property of forming a lather when agitated, like a solution of soap, whence the name of the plant was derived. This property, as well as the medical virtues of the plant, resides in a peculiar proximate principle, obtained from the root by Bucholz, and called by him sapolin. This principle constitutes, according to Bucholz, 34 per cent. of the dried root, which contains also a considerable quantity of gum and a little bassorin, resin, and altered extractive, besides lignin and water. Saponin is obtained, though not absolutely pure, by treating the watery extract with alcohol and evaporating. It is brown, somewhat translucent, hard and brittle, with a sweetish taste, followed by a sense of acrimony in the fæces. It is soluble in water and officinal alcohol, but is insoluble in anhydrous alcohol, ether, and the volatile oils. Its watery solution froths when agitated. This principle has been found also in various other plants, as different species of Silene, Dianthus, Lychnis, and Anagallis. (Journ. de Pharm., 2e sér., x. 339.) It is said to possess poisonous properties. Soap-
wurt has been used in Germany as a remedy in venereal and scrofulous affections, cutaneous eruptions, and visceral obstructions. It appears to act as an alternative, like sarsaparilla, to which it has been deemed superior in efficacy by some physicians. The plant is given in the form of decoction and extract, which may be freely taken. From two to four pints of the decoction daily are recommended in lues. The insipiated juice, given in the quantity of half an ounce in the course of a day, is said by Andry generally to cure gonorrhoea in about two weeks, without any other remedy. According to Dr. Bonnet and M. Malapert, this and other plants containing saponin are capable of producing poisonous effects. (Journ. de Pharm., 3e sér., x. 339.)

SARCOCOLLA. A peculiar vegetable product, exuding spontaneously from the Pentas Sarcocolla, P. mucronata, and other species of Pentas, small shrubs growing at the Cape of Good Hope, in Ethiopia, Arabia, &c. It is in the form of small, roundish, irregular grains, sometimes agglutinated in masses, friable, opaque or semi-transparent, of a yellowish or brownish-red colour, inodorous unless heated, when they have an agreeable smell, and of a peculiar, bitter, sweetish, and acrid taste. Sarcocolla, according to Pelletier, consists of 65-3 per cent. of a peculiar substance, considered by Dr. Thomson as holding an intermediate place between gum and sugar, and called sarcocolin or pure sarcocolla, 4-6 of gum, 3-8 of a gelatinous matter having some analogy with bassorin, and 28-8 of lignin, &c. It is said to be purgative, but at the same time to produce serious inconvenience by its acrid properties. The Arabian physicians used it internally; and by the ancients it was employed as an external application to wounds and ulcers, under the idea that it possessed the property of agglutinating the flesh, whence its name was derived. It is out of use.

SARRACENIA. Side-saddle Plant. Fly-trap. Two Southern species of this curious indigenous genus of plants, S. juba and S. cartolaris, were brought into notice by Dr. F. P. Porcher, in a communication published in the Charleston Medical Journal and Review. Dr. Porcher states that the roots (rhizomes) of these plants have long been used as a domestic remedy by the inhabitants of the lower portions of South Carolina. The medicine is believed in that region to possess extraordinary powers in dyspepsia; and he received reports, from persons entirely deserving of confidence, of its efficacy in sick-headache, waterbrash, gastralgia, abdominal distension, &c. In trying the remedy upon himself, he found it to be bitter and astringent to the taste, and, in its effects on the system, stimulant to the stomach, the circulation, and in some degree to the brain, and at the same time to a certain extent diuretic, and disposed to operate mildly on the bowels. From the results stated by Dr. Porcher, we should infer that the medicine is a stimulating tonic, with some tendency to act on the brain; and probably well suited to cases of dyspepsia dependent on debility of stomach. Professor Sheppard submitted the root to chemical examination, and found it to contain lignin, colouring matter, resin, an acid salt of lime, and a salt probably of an organic alkali. The best mode of administration seems not to have been well determined. Invalids chew it as they would chew tobacco; and from Dr. Porcher's statements we should infer that it might be appropriately given in powder, in the dose of half a drachm three or four times a day. (See Wood's Quarterly Retrospect, ii. 78.) Much attention has recently been paid to another species of Sarracenia, the S. purpurea, in the treatment of smallpox, under the impression that it had the power of very favourably modifying that disease, and, indeed, of materially shortening its course. The claims made in favour of this remedy were so much in opposition to all that we knew, whether of the medicine or the disease, that we had no hesitation in expressing our conviction, that the apparent efficacy of the remedy was simply owing to its employment in those cases of modified smallpox, which, in consequence of a partial protection of the system, either through vaccination or a previous attack of smallpox, generally run a short, and almost always a favourable course; and subsequent experience has fully determined its entire want of any curative influence over the disease. The root was exhibited in infusion or decoction, made in the proportion of half an ounce to a pint of water, and given in the dose of a wineglassful every three hours. The whole herbaceous part of the plant, having been found to possess the same bitter taste, was afterwards used in the same manner and dose. For a description of this species of Sarracenia, in all its relations, see a paper by Prof. Bentley, in the Pharmaceutical Journal for Jan. 1863 (p. 294).

SASSA GUM. This name has been applied by Guibourt to a gum, occasionally brought into market from the East, and answering so exactly to Bruce's description of the product of a tree which he calls sassa, that there is reason to believe in their identity. According to Guibourt's description, it is in mammillary masses, or in convoluted pieces resembling an ammonite, of a reddish colour and somewhat shining surface, and more transparent than tragacanth. Its taste is like that of tragacanth, but slightly acrid. When introduced into water, it becomes white, softens, and swells to four or five times its original bulk; but it preserves its shape, neither like tragacanth forming a mucilage, nor like Bassora gum separating into distinct flocculi. It is rendered blue by iodine.

SASSY BARK. This bark is interesting chiefly from its employment by the natives of Western Africa as an ordeal in their trial for witchcraft or sorcery. Specimens sent to this
country from Liberia were first examined by Mr. C. A. Santos, who published his observations in the *Am. Journ. of Pharm.* (xii. 97, April, 1849). Other specimens, both of the bark and the plant producing it, afterwards came under the notice of Professor Procter, who was thus enabled to determine as well the chemical characters as the botanical source of the product. His papers on the subject are contained in the same journal (xxiii. 301, and p. 195); and in the last is given a botanical description of the tree. To these papers the reader is referred for particular information on the subject. The bark was thought to be the product of a previously undescribed species of *Erythrophleum*, for which Prof. Procter proposed the name of *E. judiciale*. It appears, however, from a note of Prof. Lindley, published in the *Pharmaceutical Journal* for January, 1857 (p. 378), that the tree had been previously described under two specific names, having been noted in Hooker's *Niger Flora* (p. 329) as the *Erythrophleum Guineense* of Don, and the *Filicae Filiculoides* of Guillemin and Perrotet's *Flora of Senegal*; facts, of course, unknown to Prof. Procter when his papers were written. It is a large tree with spreading branches, doubly pinnated leaves, flowers in spike-like racemes, and leguminous fruit. The bark is in pieces more or less curled, with or without epidermis, in the former case somewhat fissured externally, of a dull-red colour diversified by whitish spots, brittle, presenting when cut transversely numerous fawn-coloured spots surrounded by reddish-brown tissue, nearly inodorous, of an astringent taste, and, according to Mr. Santos, of the sp. gr. 1-054. Prof. Procter found it to contain tannic acid, insoluble apothemalogueous to that of *Rhatany*, a red colouring matter formed by a combination of the two preceding constituents, gallic acid, gum, a little resin, fatty matter, various salts, and a peculiar substance precipitable by tannic acid, and soluble in alcohol and chloroform. He did not isolate the active principle. The bark yields its virtues to water. In reference to its effects on the system it has been considered as emetic and cathartic, with some influence over the cerebral functions; but little was certainly known. Professor Procter found three grains of the aqueous extract, given to a cat, to produce prostration, frothing at the mouth, dilatation of the pupils, and total loss of inclination to eat. Largely taken the bark was known often to cause death. The powder sniffed up the nostrils occasions violent sneezing. Some experiments made with it by Drs. S. Weir Mitchell and W. A. Hammond have given us more precise knowledge in regard to its properties. From these it appears to be nauseating and emetic, narcotic, and astringent, but without any cathartic power. The same writers give the following as the result of the observation of Dr. Savage made in Africa, and communicated to them. When the bark is chewed, it causes a feeling of constriction in the fauces, attended with prickling, and followed by numbness. A strong infusion or decoction occasions stricture across the brow, severe pain in the head, coma, and death. Independently of its use by the natives as an ordeal poison, it is sometimes employed by them as a remedy in dysentery, diarrhea, and colic. Dr. Savage himself has known it to be successful in intermittent fever, dysentery, and diarrhoea. A grain of the watery extract was given for a dose every three hours. (*Charleston Med. Jour.*, Nov. 1859, p. 735.)

**SATUREJA HORTENSIS. Summer Savory.** An annual labiate plant, growing spontaneously in the south of Europe, and cultivated in gardens as a culinary herb. It has an aromatic odour and taste, analogous to those of thyme, and was formerly used as a gentle carminative stimulant; but is now employed only to give flavour to food. *S. montana* or *winter savory*, which is also cultivated in gardens, has similar properties.

**SCOLEPENDRIUM OFFICINARUM.** Smith. *Asplenium Scolependrium* Linn. *Harts-tongue*. A fern indigenous in Europe and America. Its vulgar name was derived from the shape of its leaves, which were the part formerly used in medicine. They have a sweetish, mucilaginous, and slightly astringent taste, and, when rubbed, a disagreeable oily odour. They were used as a deobstruent in visceral affections, as an astringent in hemorrhages and fluxes, and as a demulcent in pectoral complaints; but their properties are feeble, and they have fallen into neglect.

**SERPHELARIA NODOSA. Figwort.** The root of the *knotty-rooted* *figwort* is perennial, tuberous, and knotty; the stem is herbaceous, erect, quadrangular, smooth, branching, and from two to three feet high; the leaves are opposite, petiolate, ovate-cordate, pointed, sharp-toothed, reined, and of a deep-green colour; the flowers are small, dark-purple, slightly drooping, and borne on divided peduncles in erect terminal branches. The plant is a native of Europe, where it grows in shady and moist places, and flowers in July. The leaves, which are the part used, have when fresh a rank fetid odour, and a bitter somewhat acid taste; but these properties are diminished by drying. Water extracts their virtues, forming a reddish infusion, which is blackened by the sulphate of the sesquioxide of iron. Wall has obtained from them two proximate principles, which he names respectively *serpularin* and *serpularosamin* (*Mayer, Am. Journ. of Pharm.*, July, 1863, p. 295.) Figwort leaves are said to be anodyne and diuretic, and to have repellent properties when externally applied. They were formerly considered tonic, diaphoretic, discutient, antihelmintic, &c., and were thought to be useful in scrofula. They are at present very little employed; but in Europe they are sometimes applied, in the form of ointment or fomentation, to piles, painful tumours and ulcers, and cutaneous eruptions.

---

**PART III. Satureja Hortensia.—Serpularia Nodos.**

---

1597
SCUTELLARIA LATERIFLORA. Scutell. This is an indigenous perennial herb, belonging to the Linnæan class and order Didynamia Gymnosperma, and to the natural order Labiate. Its stem is erect, much branched, quadrangular, smooth, and one or two feet high. The leaves are ovate, acute, dentate, subordicate upon the stem, opposite, and supported upon long petioles. They are small, of a pale-blue colour, and disposed in long, lateral, leafy racemes. The calyx has an entire margin, which, after the corolla has fallen, is closed with a helmet-shaped lid. The tube of the corolla is elongated, the upper lip concave and entire, the lower three-lobed. The plant grows in moist places, by the sides of ditches and ponds, in all parts of the Union. To the senses it does not indicate, by any peculiar taste or smell, the possession of medicinal virtues. It is even destitute of the aromatic properties which are found in many of the labiate plants. When taken internally, it produces no very obvious effects. Notwithstanding this apparent inertness, it obtained, at one period, extraordinary credit throughout the United States, as a preventive of hydrophobia, and was even thought to be useful in the disease itself. A strong infusion of the plant was given in the dose of a teacupful, repeated several times a day, and continued for three or four days after the bite was received; while the herb itself was applied to the wound. Strong testimony was adduced in favour of its prophylactic powers; but it has already shared the fate, which in this case is no doubt deserved, of numerous other specifics against hydrophobia, which have been brought into temporary popularity, only to be speedily abandoned. Nevertheless, it is thought by some practitioners to have valuable therapeutic properties; and Drs. Ariel Hunton and C. H. Cleaveland, of Vermont, speak in strong terms of its efficacy as a nervine. They have employed it in neuralgic and convulsive affections, chorea, delirium tremens and nervous exhaustion from fatigue or over-excitement, and have found it highly advantageous. Dr. Cleaveland says that he prefers it to all other nervines or antispasmodics, except where an immediate effect is desirable. He prefers the form of infusion, which he prepares by boiling half an ounce of the dried leaves to a teacupful of water, and allows the patient to drink ad libitum. (Am. Journ. of Pharm., xxiii. 370, from N. Y. Register of Med. and Pharm., also N. J. Med. Reporter, v. 13.) Two preparations are now used; one called scutellaria, though erroneously, as it has no claim to be considered a pure proximate principle, the other a fluid extract. The so-called scutellaria is prepared by mixing a concentrated tincture with water, precipitating by alum, and then washing and drying. Dr. Cleaveland gives it in a dose varying from one to three or four grains, and finds many happy effects from it in quiting nervous disorders. (N. J. Med. Reporter, viii. 121.) The fluid extract, prepared by the Messrs. Tilden, is used in the dose of one or two fluidrachms. Dr. Joseph Bates, of New Lebanon, N. Y., speaks highly of it as a nervine. (Bost. Med. and S. Journ., iii. 387.) The Scutellaria gaterifolia, or common European scutell, which also grows wild in this country, has a feeble, somewhat alliaceous odour, and a bitterish taste. It has been employed in intermittents, and externally in old ulcers, but is now out of use. Dr. W. E. Evans, of Canada West, has found it useful in epilepsy; but to effect a cure it must be continued, he says, for five or six months. He makes an infusion with two ounces of the herb and eight ounces of water, and gives a fluidounce every eight hours, doubling the quantity after a week. (See Am. Journ. of Med. Sci., xvii. 495.) Another indigenous species, the S. integrifolia, of which S. hyosopfolia, Linn., is considered by some as a variety, is intensely bitter, and might probably be found useful as a tonic.

SECALE CEREALE. Rye. Syria, Armenia, and the southern provinces of Russia have been severally indicated as the native country of rye. The plant is now cultivated in all temperate latitudes. The grains consist, according to Einhof, of 24-2 per cent. of envelope, 65-6 of flour, and 10-2 of water. The flour, according to the same chemist, consists of 61-07 per cent. of starch, 9-48 of gluten, 3-28 of albumen, and 3-28 of uncrystallizable sugar, 11-09 of gum, 6-38 of vegetable fibre, besides 6-02 of loss, comprising an acid, the nature of which was not determined. Rye flour has been much used, in the dry state, as an external application to erysipelas inflammation, and other eruptive affections, the burning and unpleasant tingling of which it tends to allay, while it absorbs the irritating secretions. In the form of mush, it is an excellent laxative article of diet, and, mixed with molasses, it may be given with great advantage in hemorrhoids and prolapsus ani, connected with constipation. Rye carbonized by heat, with exclusion of the air, has been highly recommended as a tooth-powder.

SEDUM ACRE. Biting Stone-crop. Small Houseleek. A small, perennial, succulent European plant, growing on rocks and old walls, with stems about as long as the finger, and numerous very minute leaves. It is inodorous, and has a taste at first cooling and herbaceous, afterwards burning and durably acid. Taken internally it vomits and purges, and, applied to the skin, produces inflammation and vesication. The fresh herb and the expressed juice have been used as an antiscorbutic, emetic, cathartic, and diuretic, and have been applied locally to old ulcers, warts, and other excrescences; but the plant is at present little employed. It has recently been recommended in Germany as a remedy in epilepsy. Other species are less acrid, and are even eaten as salad in some parts of Europe.
Selenium Palustre.—Silene Virginica.

Such are Sedum rupestre and S. album. S. Telephium was formerly employed externally to cicatrise wounds, and internally as an astringent in dysentery and haemoptysis; and is still esteemed by the common people in France as a vulnerary.

Selenium Palustre. (Linn.) Peucedanum montanum. (Lindley, Flor. Med.) Marsh Parsley. Persil de maraîche. (Fr.) This is an umbelliferous plant, belonging to the Umbellaria Digynia in the Linnaean system. It is herbaceous, with a fleshy, lacteascant root, from which rises annually a single fistulous stem, about four feet high, furnished with large, soft, smooth, bipinnate or tripinnate leaves, and branching at top, with terminal umbels, each consisting of thirty small white flowers. The plant frequents low wet grounds in the north of Europe. The root is the part used. This, when dried, is of a brown colour externally, of a strong aromatic odour, and an acid, pungent, aromatic taste. The powder is of a light grayish-yellow colour. Analyzed by Peschier, it was found to contain a volatile oil, a fixed oil soluble in ether and alcohol, gum, a yellow colouring substance, a nitrogensous, mucose-saccharine principle, a peculiar acid which he calls selinit, phosphate of lime, and lignin. The root of Selenium palustre has long been a popular remedy for epilepsy in the Russian Province of Courland; and, having in 1806 attracted the attention of Dr. Trinius, a Russian physician, was by him in 1818 brought before the notice of the profession, and afterwards acquired some reputation in the treatment of that disease. It did not, however, long retain this reputation, and in a few years seems to have been quite forgotten. Recently, its use has been revived by Dr. Th. Herpin, who published a memoir upon the subject in 1859, speaking in decidedly favourable terms of its efficiency. In relation to its physiological effects, it seems to exercise no very obvious influence on the system, sometimes acting as an aperient, in a very few instances causing temporary nausea or gastric uneasiness, but in many cases passing through the alimentary canal without apparent effect, and never, however long continued, producing any derangement of the general health. It seems to act favourably on the menstrual function, restoring its regularity, and relieving the pains often attendant on it. In speaking of its use in epilepsy, Dr. Herpin ranks it as the fourth in value, estimating oxide of zinc, sulphate of copper, and valerian, in the order of their succession, and next Selenium. He has also used it with apparent advantage in hooping-cough, and recommends its trial in other nervous affections. The commencing dose in epilepsy is from 20 to 30 grains three times a day, taken before breakfast and dinner, and at bedtime; and increased by one-half every week, until the original dose is quadrupled; after which it may be continued for six weeks or longer. For children the dose is to be diminished according to the age. (J. d'Pharm., Juillet, 1859, p. 16.)

Sempervivum Tectorum. Common Houseleek. A perennial, succulent, European plant, growing on rocks, old walls, and the roofs of houses, and remarkable for its tenacity of life. It is occasionally cultivated in this country as an ornament to the walls of houses, or as a domestic medicine. The leaves, which are the part used, are oblong, pointed, from half an inch to two inches in length, thick, fleshy, succulent, flat on one side, somewhat convex on the other, smooth, of a light-green colour, inodorous, and of a cooling, slightly saline, astringent, and sourish taste. They contain a large proportion of superfluous of lime. They are employed, in the recent state and bruised, as a cooling application to burns, stings of bees, hornets, &c., ulcers, and other external affections attended with inflammation. The juice is said to cure warts.

Senecio Vulgaris. Common Groundsel. An annual European plant, introduced into this country, and growing in cultivated grounds. The whole herb is used, and should be gathered while in flower. It has, when rubbed, a peculiar rather unpleasant odour, and a disagreeable, herbaceous, bitterish, and saline taste, followed by a sense of astringency. It is emetic in large doses, and has been given in convulsive affections, liver complaints, spitting of blood, &c., but is now very little used. The bruised herb is sometimes applied externally to painful swellings and ulcers. The plant is employed also as food for birds, which are fond of it. Other species of Senecio have been medicinally used; and an indigenous species, the S. aures or raywort, is said by Schoepf to be a favourite vulnerary with the Indians. The "eclectics" consider it emmenagogue, and use it not only to stimulate the function, but to regulate it when in excess or otherwise deranged. They also believe it to possess diuretic properties, and to be useful in disorders of the urinary organs. They give the name of senna to a preparation made by precipitating the tincture with water; but this medicine should be reserved for the active principle when discovered. The whole plant is used in decoction or infusion, which may be taken freely.

Sienna. Terra di Sienna. An argillaceous mineral, of a fine texture, very light, smooth, and glossy, of a yellowish-brown or coffee-colour, leaving a dull-orange trace when moistened and drawn over paper. By calcination it assumes a reddish-brown colour, and is then called burnt sienna. In both the raw and burnt states it is used in painting. The best sienna is brought from Italy, but an inferior kind is found in England.

Silene Virginica. Catchfly. Wild Pink. An indigenous perennial plant, growing in Western Virginia, the Carolinas, and in the States beyond the Alleghany mountains. Dr.
Barton, in his "Collections," states that a decoction of the roots is said to be efficacious as an anthelmintic. We are told that it is considered poisonous by some of the Indians. S. Pennsylvanica, which grows in the Eastern section of the Union, from New York to Virginia, probably possesses similar properties.

SILEX, PULVERIZED. Silex Contritus. Lond. Silicic Acid. In operations of pharmacy, substances are sometimes employed whose action is exclusively mechanical. Thus, in the U. S. Pharmacopoeia, sand was used in preparing oil of amber and the fluid extract of rhubarb, and carbonate of magnesia is now used in forming several of the medicated waters. The use of the same carbonate was also directed in the London Pharmacopoeia of 1826, in alternative processes for preparing several of these waters. Mr. R. Warington objected to the use of this carbonate, as being dissolved to an injurious extent, and proposed to substitute porcelain clay, or pulverized silice, glass, or pumice stone. The London College, probably influenced by this objection, abandoned, in its Pharmacopoeia of 1851, the use of carbonate of magnesia, and substituted finely pulverized silex, under the name of Silex Contritus. This powder may be conveniently obtained from colourless quartz or rock-crystal. In order to render the mineral more easily pulverizable, it is advantageous to heat it to redness, and quench it in water. It may then be reduced to fine powder in a porphyry or agate mortar. The London College prepared all the medicated waters, except two, from the volatile oils of the plants, in addition to the method of distillation with water from the plants themselves. When the volatile oils were used, pulverized silex was directed as a mechanical agent. The oil was rubbed up first with the silex and then with the water, and the whole was filtered. The silex acted by minutely dividing the oil and diffusing it through water, and, by the subsequent filtration, was entirely removed.

Pulverized silex is a harsh, white, tasteless powder, insoluble in water and most other solvents. Its sp. gr. is 2.66. In composition it is a tetroxide of silicon, SiO₂. A protoxide (SiO) has been discovered by Wöhler. (Chem. Gaz., May 15, 1857.) Silicon is a non-metallic element, which has been obtained in three allotropic states, called amorphous, graphitoidal, and octahedral silicon; the first corresponding to charcoal, the second to graphite, and the third to diamond. The octahedral crystallizes like diamond with curved facets, is hard enough to scratch glass but not topaz, and has the sp. gr. 2.49.

SILICATE OF SODA. Soda Silicus. Soluble Glass. This is the salt employed by MM. Socquet and Bonjean, in conjunction with benzoate of soda, in the treatment of gout and rhematism, for the purpose of eliminating uric acid by the urine. (See page 147.) It is made by fusing one part of silica and two of dried carbonate of soda, mixed in powder, in an earthenware crucible, and pouring out the fused mass on a stone slab to cool. This is pulverized, and treated with boiling water, to dissolve the soluble part. The solution is filtered and concentrated, so as to form crystals on cooling. These are then purified by dissolving them in water heated to 100°, filtering the solution, and concentrating it so that it may recrystallize. Silicate of soda is supposed to promote the discharge of uric acid by the kidneys; while the benzoate of soda transforms the same acid into hippuric acid. This action of the latter salt is doubtful; as it is well known that benzoic acid, when taken, is always changed into hippuric acid, the presence of which in the urine is more plausibly attributed to the medicine than to the transformation of uric acid.

SISYMBRIUM OFFICINALE. Scopoli. Erysimum officinale. Linn. Hedge Mustard. A small annual plant, growing in the United States and Europe, along the roadsides, by walls and hedges, and on heaps of rubbish. It has an herbaceous somewhat acrid taste, which is strongest in the tops and flower-spikes, and resembles that of mustard, though much weaker. The seeds have considerable pungency. The herb is said to be diuretic and expectorant, and has been recommended in chronic coughs, hoarseness, and ulceration of the mouth and fauces. The juice of the plant may be used mixed with honey or sugar, or the seeds may be taken in substance. Sisymbrium Sophia, or the flax weed, was formerly official. It is of a pungent odour when rubbed, and of an acrid biting taste. The herb has been used externally in indolent ulcers, and the seeds internally in worms, calculus complaints, &c. Sisymbrium muralis (Ditoplaezis muralis, P. Robert) has been recently used in France in scurry, scrofula, and other echegetic affections, especially associated, in the form of syrup, with iodide of potassium. (Ann. de Thérap., 1864, p. 126.)

SIUM NODIFLORUM. Water-parsnep. A perennial, umbelliferous, aquatic European plant; growing also in the southern section of the United States, where it is supposed to have been introduced. It is commonly considered poisonous; but the expressed juice, given by Withering in the dose of three or four ounces every morning, was not found to affect the head, stomach, or bowels. He found it, in this quantity, very advantageous in obstinate cutaneous diseases; and the plant has been usefully employed by others in similar complaints, and in scrofulous swellings of the lymphatic glands. It is considered diuretic. Sium latifolium, which grows in Europe and the United States, and is the common water-parsnep of this country, is positively asserted to be poisonous; and madness and even death are said to have followed the use of the root. The S. Sisarum or skirtet, a plant of Chinese
PART III.  

Small.—Soot.

1601

origin, cultivated in Europe, has a sweetish, somewhat aromatic root, which is employed as food in the form of salad, and is supposed to be a useful diet in complaints of the chest.

W.

SMALT. Azure. When the impure oxide of cobalt, obtained by roasting the native arseniuret of that metal, is heated with sand and potassa, the mixture melts, and a beautiful blue glass results, which, when reduced to powder, receives the name of smalt or azure. It is used chiefly in painting.

W.

SOAP BARK. This is the product of Quillaya Saponaria, an evergreen tree, growing in the mountains of Chili, in South America, and known to the inhabitants by the name of quillay, said to be derived from the Chilian word quillean, which signifies to wash. It is the liber or inner bark that is employed, the outer dead layers being rejected. When bruised, and macerated in water, it imparts to that liquid the property of frothing like soap, when agitated. This has been found by MM. Fleury jun. and Boutron Chalard to be owing to the existence of saponin in the bark, the same principle as that which gives a similar property to Saponaria officinalis. The bark contains neither tannic acid nor any bitter principle. It is much used along the western coast of South America, where it constitutes an article of commerce; and we are informed that it is also imported into this country, being employed for cleansing cloth from grease. According to Mr. Charles Raymond, the people of Chili use it in washing silken and woollen stuffs, when it is desirable not to change their colour, and still more for cleansing the hair, which it is supposed to beautify and preserve. On the same authority, it is stated to be sometimes given as a febrifuge, and as a remedy in colds in the head. For the latter purpose, its powder is snuffed up the nostrils. It causes sneezing and profuse nasal discharge. (Journ. de Pharm., xxxii. 220; also Am. Journ. of Pharm., xxix. 104.)

W.

SOLUBLE MERCURY OF HAHNEMANN. This is prepared by adding, drop by drop, a dilute solution of ammonia to an equally dilute solution of nitrate of protoxide of mercury, until the precipitate begins to be paler than at first. It is a black powder, which has usually the composition, expressed by the formula NH₄·3HgO·NO₃. It is, therefore, an ammoniated nitrate of protoxide of mercury. When it has a grey colour, the fact shows that too much ammonia has been employed in its precipitation. This preparation is included in the French Codex. It has been used in syphilitic diseases.

B.

SOOT. Fuluió Ligni. This well-known substance has a peculiar smell, and a bitter, empyreumatic, and disagreeable taste. Its composition is very complex. Reduced to powder, and treated with water, it affords an infusion of a deep-yellow or brown colour, which is deeper if heat is employed. The insoluble portion amounts to about 44 per cent. The soluble part consists chiefly, according to Berzelius, of a pyrogenous resin unitied with acetic acid (acid pyretn), saturated with potassa, lime, and magnesia. It also contains sulphate of lime, chloride of potassium, acetate of ammonia, and traces of nitric acid. When the solution is evaporated to dryness, it furnishes a black extract. This forms with water a blackish-brown solution, which, when treated with any free acid except the acetic, lets fall the acid pyretn, in the form of a black mass resembling pitch; while the acetic employed remains in solution with the bases previously in combination with the pyretn. Bracconnot has shown that he had discovered in pyretn a peculiar principle, which he named as-elm-pyretin, but Berzelius believed he was mistaken. Besides these substances, Bracconnot ascertained the existence in soot of an arotized extractive matter to the amount of 20 per cent. This matter, when submitted to dry distillation, afforded a considerable proportion of pyrogenous oil. Soot itself, when subjected to a similar distillation, furnishes one-fifth its weight of empyreumatic oil. To the above ingredients of soot must be added creasote, to the presence of which it is supposed to owe its medicinal properties.

Soot was formerly official with the Edinburgh College, and the Scotch physicians were in the habit of frequently prescribing it as a tonic and antispasmodic in the form of tincture. It went very much out of use in regular practice; but came again into vogue after the discovery of creasote, which is one of its ingredients. At present it is chiefly used as an external remedy in the form of decoction or ointment. In the Revue Méd. for June, 1834, M. Baud details a number of cases of various affections, such as obstinate tetters, porrigo favosa, psora, fistula, cancerous and venereal ulcers, chronic irritations of the lining membrane of the mouth, exudations from the mucous membrane of the nose, herpetic eruptions of the genital organs, and pruritus of the vulva, in which the use of soot effected cures. The decoction is made by adding two handfuls of soot to a pint of water, boiling for half an hour, and filtering. It is applied as a lotion to the affected parts, or injected into the fistulas several times a day; and, in the intervals, the part, if accessible, is dressed with an ointment, made by rubbing up a drachm of finely powdered soot with an ounce of lard. In cases of porrigo, the crusts must be removed by poultices before the soot is applied. In treating obstinate cases of chronic eczema, M. Bougard, of Belgium, has been very successful with the use of a mixture of equal parts of soot and glycerin. In serofulous opthalmia, M. Caron Duvillards and M. Baudeloque have found a collyrium, 101
made according to the following formula, very useful. Infuse two ounces of soot in boiling water, filter the solution, and evaporate it to dryness. Dissolve the dry residue, with the assistance of heat, in strong white wine vinegar, and add extract of roses in the proportion of twenty-four grains to twelve fluidounces of the liquid. It is prepared for use by adding a few drops of the liquid to a glass of water. (Bull. Gén. de Thérapeutique, March, 1834.)

This formula is not very satisfactory; as it does not indicate the proportion of vinegar to be employed. In a case of severe and extensive burn, in which, after the separation of the sloughs, the patient began to sink from the profuse discharge, Dr. Ebers, of Bordeaux, found advantage from the application, to the granulating surface, of lint soaked in a decoction of soot. It reduced the discharge in a surprising manner, and promoted cicatrization.

The late Dr. Hewson, of this city, found an infusion of soot an efficacious remedy, employed by injection, in cases of ascarides. In one case of long standing in an adult, in which a number of remedies had been tried unsuccessfully, injections of soot daily, persevered in for two weeks, effected a complete cure. The injection was made by adding a cupful of soot to a pint of boiling water, and straining the solution. An infusion of hickory ashes and soot is used in this city as a popular remedy for dyspepsia. It is made by infusing a pint of clean hickory ashes and a gill of soot in half a gallon of boiling water, allowing the liquor to stand for twenty-four hours, and then decanting. Of this a small wineglassful is taken three or four times a day. No doubt this infusion has been useful in acidity of stomach; but its indiscriminate use in the various gastric affections, popularly confounded under the name of dyspepsia, is calculated to do much harm. Soot is decidedly antiseptic. A few shovelfuls of it, thrown into privies or drains, effectually destroy their foul exhalations.

SORBUS AUCUPARIA. Mountain Ash. A small European tree, of the family of Rosaceae, distinguished by its pinnate leaves, somewhat resembling that of the ash, and by its beautiful clusters of scarlet fruit, about as large as peas, which give it a striking appearance, and have caused it to be cultivated in gardens and ornamented grounds. We have an American species, S. Americana, which is similarly characterized, and is highly ornamental to our mountain regions in autumn and winter by its bright scarlet fruit. The fruits of the European plant, and the same is probably the case with our own, contain a peculiar kind of sugar called sorbin, susceptible of the vinous fermentation; and an alcoholic drink has been prepared from them. They seem to have been used for preparing malic acid; and Dr. Hofmann has recently discovered in them two new acids, which he designates as sorbic and parasorbic acids. (See Pharm. Journ., May, 1859, p. 573.) They have been used in scurvy, and, in infusion, as a remedy in hemorrhoids and strangury. All parts of the tree are astringent, and may be employed in tanning, and dyeing black.

SORGHUM SACCHARATUM. Sorghum. Chinese Sugar-cane. This most valuable plant, indigenous in India, China, and other parts of the East, has within a few years been introduced into Europe and the United States. It was not till 1851 that the seeds were first sent to France from China; and so late as 1855 only a few acres were cultivated. In 1854 some seeds were brought to the United States by Mr. D. Jay Browne, for the Patent Office, from France, and were distributed to different persons through the country. (H. S. Olcott.) The sorghum is now very largely cultivated in this country and in France, and there has probably been no instance in which a plant has more rapidly grown into general favour, as an object of agriculture, than this. Barth, in his Travels in Africa (Am. ed., ii. 359), states that it is extensively cultivated in the interior of that continent. It ranks next in value with the Gramineae, and belongs to Polygania Monoea in the Linnean system. It is an annual plant, with a jointed stem from eight to fifteen feet or more in height, furnished with alternate, sheathing, ensiform leaves, two or three feet long by about two inches or more in breadth, and ending in a panicle of flowers arranged in spikelets, each composed of three to five flowers, of which one only is fruitful. The glumes, which envelope the fruit at maturity, are of a deep-brown colour, which is characteristic of the species. The seeds, which are about as large as millet seeds, are planted in the spring in rows, like Indian corn, and the plant attains maturity in September or October. It is valued chiefly for the saccharine product of its stems, but other parts also are used. The seeds, though not fitted as food for man, answer well for poultry and domestic animals generally; the leaves, stripped from the stem and dried, make an excellent winter fodder for cattle; and we have been informed that the stems, when deprived of their juice, are sold to the paper-makers. Prof. Hété, of the Medical School of Toulon, has found in the glumes of the seeds two colouring principles, one red, only slightly soluble in water, but readily dissolved by alcohol, ether, and acid and alkaline solutions, the other yellow, very soluble in water and the other menstrua mentioned, both of which may be used in dyeing, and might be substituted for madder (Journ. de Pharm., Avril, 1859, p. 262.) The stem abounds in juice, which becomes more and more saccharine with the growth of the plant. The proportion of juice is 80 or 90 per cent., and of sugar on the average about 7, though it may reach 10 or 15 per cent. (Hété, Ibid., p. 258.) According to M. Lepay, who has been largely concerned in the manufacture of alcohol and sugar from the sorghum, the period at which the stem yields most sugar is when the seeds are quite ripe yet not hardened, and before the stem has
lost its green colour. He also determined by his experiments that, though the juice before this period is less rich in proper sugar of cane or crystallizable sugar, which in solution turns the plane of polarization to the right, yet it contains uncrystallizable sugar capable of conversion into alcohol, and may be profitably employed for this purpose. M. Leplay thinks that the whole of the saccharine matter of the juice, when the seeds are perfectly ripe, is crystallizable, and exists in a proportion often exceeding 15 per cent. Another important fact stated by M. Leplay, is that the sorghum stalks, if carefully dried, loss none of their sugar, and may thus be advantageously carried from various points of production to central manufacturing establishments. (Ibid., 5e sér., xxxii. p. 342.) If these facts shall be found applicable to the sorghum as cultivated in this country, there is little doubt that the plant will some time be largely employed for the preparation of sugar, should the supply of that from the cane be from any cause insufficient to meet the demand. From experiments by Dr. C. M. Wetherill, the results of which are published in the official U. S. Patent Office Report for 1862 (p. 523), it appears that 17 different specimens of juice, from different parts of the U. States, yielded an average of 4-82 per cent. of crystallizable sugar, 6-46 per cent. of uncrystallizable sugar, and 11-25 per cent. of both kinds. But we are not informed at what period, precisely, in reference to the maturity of the seeds, the juice was expressed; so that there are no grounds for comparison with the results obtained by M. Leplay. At present the sorghum is used almost exclusively in the preparation of molasses, vast quantities of which are made in the United States, sufficient in many instances to meet the wants of the whole neighbourhood. The molasses is prepared by expressing the stems, between rollers, in a machine worked either by the hand, or by horse or steam power, and submitting the juice to ebullition, in order to concentrate it sufficiently, and at the same time coagulate any albuminous matters that may happen to be contained in it. The addition of a little lime to the juice before boiling will prove useful, both by neutralizing acid, which would give a tendency to the saccharine matter to pass into glucose, and by combining with organic principles which interfere with clarification. From what has been above stated, it will be inferred that, when molasses merely is wanted, or when the object is to obtain alcohol or vinegar, it will not be necessary to wait till the seeds are perfectly ripe; and thus a late crop may be made useful, though insufficiently advanced to ripen before frost. For the manufacture of sugar, the stems should not be pressed until the maturity of the fruit.

Another plant, called imphee or African sugar-cane, has been recently cultivated to a considerable extent for the same purposes as the sorghum. It is a native of Africa, where it is said to be cultivated by the Kaffirs. Its botanical characters do not seem to be well determined, though considered by Mr. Leonard Wray as a Holcus, and specifically designated as Holcus saccharatus. (Olcott, Sorgho and Imphee, 6th ed., p. 201.) This, however, as defined by Linnaeus, is considered by some botanists as a mere synonyme of Sorghum saccharatum; and it is highly probable that the two plants are mere varieties of the same species. The seeds of the imphee were brought to this country in 1856 or 1857, and first planted in South Carolina; but we have not learned how far its cultivation has extended, nor what relative proportion it bears to that of the Chinese plant. Still another variety of sorghum has recently been introduced from the islands of the South Pacific, under the name of Otaheitan sugar-cane, and cultivated to some extent in the West. It is distinguished by its long heads, from 7 to 12 inches in length, and from 1 to 2 in thickness. This variety, however, has not yet become generally diffused. (Patent Office Report, 1862, p. 515.)

Credit is due to Mr. J. S. Lovering, of Philadelphia, for first demonstrating, in this country, that sugar might be advantageously made from the Chinese sugar-cane; and his pamphlet on the subject will be found useful by those who may purpose to engage practically in its manufacture.

SPARTIUM JUNCEUM. Spanish Broom. A small shrub, indigenous in the south of Europe, and cultivated in our gardens as an ornamental plant. The flowers are large, yellow, and of an agreeable odour. The seeds are in moderate doses diuretic and tonic, in large doses emetic and cathartic, and have been used advantageously in dropsy. The dose is from ten to fifteen grains three times a day. They may also be given in tincture.

SPONGE. Spongia. Spongia officinalis. U. S. 1850. This, being no longer recognised in the Pharmacopoeias, is transferred to this place from Part I. The sponge is now generally admitted to be an animal. It is characterized as “a flexible, fixed, torpid, polymorphous animal, composed either of reticulate fibres, or masses of small spires interwoven together, and clothed with a gelatinous flesh, full of small mouths on its surface, by which it absorbs and ejects water.” More than two hundred and fifty species have been described by naturalists, of which several are probably employed, though Spongia officinalis is the only one designated in the Pharmacopoeias. Sponges inhabit the bottom of the sea, where they are fixed to rocks or other solid bodies; and are most abundant within the tropics. They are collected chiefly in the Mediterranean and Red Seas, and in those of the East and West Indies. In the Grecian Archipelago many persons derive their support altogether from diving for sponges. When collected they are enveloped in a gelatinous coating, which forms part of the animal.
and is separated by first rubbing them with fine sand (Lander), and then washing them with water. Large quantities of the coarser kinds are imported from the Bahamas; but the finest and most esteemed are brought from the Mediterranean.

Sponge, as found in commerce, is in yellowish-brown masses of various shapes and sizes, light, porous, elastic, and composed of fine, flexible, tenacious fibres, interwoven in the form of cells and meshes. It usually contains numerous minute fragments of coral or stone, or small shells, from which it must be freed before it can be used for ordinary purposes. Sponge is prepared by macerating it for several days in cold water, beating it in order to break up the concretions which it contains, and dissolving what cannot thus be separated of the calcareous matter by muriatic acid diluted with thirty parts of water. By this process it is rendered perfectly soft, and fit for surgical use. It may be bleached by steaming in water impregnated with sulphurous acid, or by exposure in a moist state to the action of chlorine. When intended for surgical purposes, the softest, finest, and most elastic sponges should be selected; for forming burnt sponge, the coarser will answer equally well. According to Mr. Hatchett, the chemical constituents of sponge are gelatin, coagulated albumen, common salt, and carbonate of lime. Magnesia, silica, iron, sulphur, and phosphorus have been detected in it; as also have iodine and bromine, combined with sodium and potassium. From the experiments of Mr. Croockewit, it would appear that sponge is closely analogous to, if not identical with the fibroin of Mulder, differing from it only in containing iodine, sulphur, and phosphorus. (Annal. der Chem. und Pharm., xlviii. 49.) Fibroin is an animal principle, found by Mulder in the interior of the fibres of silk.

Medical Properties and Uses. Sponge, in its unaltered state, is not employed as a medicine; but, in consequence of its softness, porosity, and property of imbiving liquids, it is very useful in surgical operations. From the same qualities it may be advantageously applied over certain ulcers, the irritating sanies from which it removes by absorption. Compressed upon a bleeding vessel, it is sometimes useful for promoting the coagulation of the blood, especially in hemorrhage from the nostrils. In the shape of sponge tent it is employed for dilating sinuses. This is prepared by dipping sponge into melted wax, compressing it between two fiat surfaces till the wax hardens, and then cutting it into pieces of a proper form and size. By the heat of the body the wax becomes soft, and the sponge, expanding by the imbibition of moisture, gradually dilates the wound or sinus in which it may be placed. After having been partially charred by heat, sponge has long been used as a remedy in goitre. Its efficacy in this complaint, formerly considered doubtful by many physicians, has been generally admitted since the discovery of iodine.

Spongia Usta. U. S. 1850. Burnt Sponge. This was an official preparation of the U. S. Pharmacopoeia. The following was the formula for its preparation. "Take of Sponge a convenient quantity. Cut it into pieces, and beat it that any extraneous matters may be separated; then burn it in a close iron vessel until it becomes black and friable; lastly, rub it into very fine powder." U. S. The sponge is decomposed, the volatile matters being driven off by the heat, and a black friable coal remaining. Preuss found that, of 1000 parts of sponge submitted to calcination, 549-848 were dissipated; and the residue consisted of 227 parts of carbon and insoluble matters, 112-08 of chloride of sodium, 16-48 of sulphate of lime, 21-422 of iodide of sodium, 7-67 of bromide of magnesium, 106-2 of carbonate of lime, 35-0 of phosphate of lime, 4-78 of magnesia, and 28-75 of protoxide of iron. (Pharm. Cent. Blatt, 1857, 169.) Herberber found in burnt sponge 1 per cent. of iodide of potassium, and 0-5 per cent. of bromide of potassium. (Annal. der Pharm., xx. 204.) As the Remediate value of burnt sponge depends chiefly upon the presence of iodine, it cannot be esteemed good unless it afford purple fumes when acted on by sulphuric acid assisted by heat. It is said that the preparation is most efficient as a remedy, when the sponge is kept on the fire no longer than is necessary to render it friable. The powder is then of a much lighter colour. Guibourt recommends that the sponge selected for burning should be unwashed, of a strong odour, firm, and compact, that it should be put into a roaster like that used for coffee, and heated over a moderate fire, till it becomes of a blackish-brown colour, that it should then be removed, powdered, and enclosed in a well-stopped glass bottle. It is best when recently prepared; as the iodine is dissipated by time, and the specimens, at first richest in this principle, contain little of it at the end of a year. (Journ. de Chim. Méc., Dec. 1831.) According to Herberber, the fine and coarse sponges do not materially differ in the proportion of their organic constituents; so that the coarse may be selected for this operation. Burnt sponge has been highly recommended in goitre, glandular swellings of a scrofulous character, and obstinate cutaneous eruptions. It is most conveniently administered mixed with syrup or honey, in the form of an elctuary, with the addition of some aromatic, as powdered cinnamon. The dose is from one to three drachms.

STAPHISAGRIA. Stavesacce. The seeds of Delphinium Staphisagria. This official of the late London and Edinburgh Pharmacopoeias has been discarded in the British. For the characters of the genus Delphinium, the reader is referred to Delphinium Consolida, in Part L Delphinium Staphisagria, or stavesacre, is a handsome annual or biennial plant, one or two feet high, with a simple, erect, downy stem, and palmate, five or seven-lobed leaves, 'sup-
ported on hairy stalks. The flowers are bluish or purple, in terminal racemes, with pedicels twice as long as the flower, and bracteoles inserted at the base of the pedicel. The nectary is four-leaved and shorter than the petals, which are five in number, the uppermost, projected backward so as to form a spur, which encloses two spurs of the upper leaves of the nectary. The seeds are contained in straight, oblong capsules. The plant is a native of the south of Europe. Stavesacre seeds are about as large as a grain of wheat, irregularly triangular, wrinkled, externally brown, internally whitish and oily. They have a slight but disagreeable odour, and an extremely acrid, bitter, hot, nauseous taste. Their virtues are extracted by water and alcohol. Analyzed by MM. Lassaigne and Feneulle, they yielded a brown and a yellow bitter principle, a volatile oil, a fixed oil, albumen, an azetotized substance, a mucilaginous saccharine matter, mineral salts, and a peculiar organic alkali called delphine or delphinia, which exists in the seeds combined with an excess of malic acid. It is white, pulverulent, inodorous, of a bitter acid taste, fusible by heat and becoming hard and brittle upon cooling, slightly soluble in cold water, very soluble in alcohol and ether, and capable of forming salts with the acids. It is obtained by boiling a decoction of the seeds with magnesia, collecting the precipitate, and treating it with alcohol, which dissolves the delphinia, and yields it upon evaporation. According to M. Courbe, it is impure as thus obtained, consisting of three distinct principles: one of a resinous nature, separated from its solution in diluted sulphuric acid by the addition of nitric acid; another distinguished by its insolubility in ether, and named by M. Courbe staphisatin; and the third soluble both in alcohol and ether, and considered as pure delphinia. (Journ. de Pharm., xix. 519.)

**Medical Properties and Uses.** The seeds were formerly used as an emetic and cathartic, but have been abandoned in consequence of their violence. Powdered and mixed with lard, they are employed in some cutaneous diseases, and to destroy lice in the hair. An infusion in vinegar has been applied to the same purpose. A preparation made by mixing three parts of the seeds in fine powder with five parts of lard, and maintaining the mixture at the temperature of 212° for twenty-four hours, is recommended by Dr. Bourguignon as very efficacious in the itch. (Journ. de Pharm., 5e sér., xviii. 421.) M. Buzin has obtained good effects from the external and internal use of stavesacre in eczema. He gave the extract in the dose of a grain and a half from four to twelve times a day. (Ann. de Thérap., 1851, p. 18.) A strong tincture has been employed as an embrocation in rheumatism. In some countries the seeds are used to intoxicate fish in the same manner as Cocculus Indicus.

**Delphinia** is highly poisonous, exerting its effects chiefly on the nervous system. Experiments made by Drs. Falck and Röög on the lower animals showed that, introduced into the rectum, the cellular tissue, or the veins, it produces death by asphyxia, preceded by symptoms of local irritation, convulsive movements, and extreme anæsthesia, without apparent disturbance of the cerebral functions until the moment before death. Introduced into the stomach, it caused salivation, vomiting, and diarrhœa, without other signs of absorption. (Arch. Gén., 4e sér., xxx. 482.) Similar results were subsequently obtained by Dr. Van Prang, who found also that the nerves of motion were paralysed as well as those of sensation. After death, congestion of the cerebral membranes, heart, great veins, and liver was observed. Dr. Turbull, in his work "On the Medical Properties of the Ranunculaceæ," states that pure delphinia may be given to the extent of three or four grains a day, in doses of half a grain each, without exciting vomiting, and without producing much intestinal irritation, though it sometimes purges. In most instances it proves diuretic, and gives rise to sensations of heat and tingling in various parts of the body. Externally, it acts like vera-tria; but, according to Dr. Turnbull, produces more redness and burning, and less tingling than that substance. He has employed it in neuralgia, rheumatism, and paralysis. It may be applied by friction, in the form of ointment or alcoholic solution, in proportions varying from ten to thirty grains of the alkaloid to an ounce of the vehicle; and the friction should be continued till a pungent sensation is produced.

**STERCULIA ACUMINATA.** This is a large African tree, known as the source of the kola nuts of Guinea. As this page was going to the press, we saw the announcement, in the Pharmaceutical Journal (Feb. 1865, p. 407), that Dr. Daniell has discovered in these nuts a crystallized alkaloid, which he believes to be *caffer*, or as it is now generally called *cafeina*.

He was induced to make the examination by noticing that, after taking a decoction of the seeds, he was affected with long-continued loss of sleep.

**W.**

**SUCCINIC ACID. Acidum Succinicum.** This acid is obtained by distilling amber. (See Succinum.) The product is an aqueous solution of impure succinic acid, associated with empyreumatic oil. (See Oleum Succini.) By filtering the liquor the solution of the impure acid passes through, while the oil is absorbed by the paper. The acid may be purified by boiling the solution with nitric acid, diluted with twice its bulk of water, and then evaporating to crystallize. Should the crystals not be colourless, the treatment with nitric acid must be repeated until they are so. Succinic acid is formed artificially by the action of nitric acid on the fatty acids, and under various other circumstances. M. Desaignes obtained it from malate of lime, subjected to fermentation excited by casein. The malate was converted into succinate of lime, which was then decomposed by sulphuric acid, so as to
Sulphate of Alumina and Iron.—Sulphate of Nickel. PART III.

Succinic acid. For the details of the process for obtaining succinic acid from malate of lime, see the paper of E. J. Kohl, in the American Journal of Pharmacy for July, 1856. Succinic acid, when pure, is a white, transparent solid, crystallizing in prisms, and having a somewhat acid taste. It dissolves in five times its weight of cold, and twice its weight of boiling water. It is soluble also in alcohol, but very sparingly so in ether. Nitric acid is without action on it. It melts at 365°, and boils without alteration at 473°. It sublimes, however, at a much lower temperature. According to Wackenroder, it is sometimes adulterated with tartaric acid, soaked in oil of amber. Crystallized from its solution in water, its formula is C₄H₆O₄ + HO. The sublimed acid has the formula 2C₄H₆O₄ + HO. Some chemists double the equivalent of this acid, and make its formula C₆H₄O₆.

Succinic acid, though formerly official, is at present seldom used in medicine. It has been ascertained to be a product of vital action, having been detected by M. Heintz in the colourless liquid found in hydatid cysts of the liver. (See Journ. de Pharm., Sept. 1850.) One of its salts, succinate of ammonia, has been used with great alleged success in delirium tremens. This salt is occasionally used as a precipitant of sesquisoioxide of iron.

SULPHATE OF ALUMINA AND IRON. This double salt was brought forward by Sir James Murray, of Dublin, as an astringent, styptic, and vermifuge. His method of preparing it is not very clearly expressed; but it may be presumed to be formed by dissolving alumina and carbonate of iron, both recently precipitated, in sulphuric acid, and duly evaporating the solution. Sir James recommends it in chronic dysentery, diarrhoea, fluor albus, and the colliquative sweats and diarrhoea which attend hectic fever and consumption. Externally he found it a powerful styptic, useful as a gargle in relaxation of the tonsils and uvula, and in salivation, as an injection in hemorrhages, and as a wash for foul and flabby ulcers. The dose for internal exhibition is from five to ten grains, dissolved in some aromatic water. This salt probably consists of tersulfate of alumina, combined with tersulphate of sesquisoioxide of iron. It is, therefore, not an alum.

SULPHATE OF BARYTA. Baryta Sulphats. Ed., Dub. Having been omitted in the British Pharmacopoeia, this salt is no longer official; but, from its former position, requires a brief notice here. The native sulphate of baryta is used in pharmacy with the same view as the native carbonate; namely, to obtain chloride of barium. The U. S. Pharmacopoeia directs for this purpose the carbonate of baryta; but the Ed. and Dub. Colleges gave a separate formula for the use of either the carbonate or sulphate, at the option of the operator. (See Barii Chloridum.) Sulphate of baryta is a heavy, lamellar, brittle mineral, varying in sp. gr. from 4.4 to 4.6. It is generally translucent, but sometimes transparent or opaque, and its usual colour is white or flesh-red. When crystallized, it is usually in very flat rhombic prisms. Before the blowpipe it strongly decrепitates, and melts into a white enamel, which, in the course of ten or twelve hours, falls to powder. It is thus partially converted into sulphuret of barium, and, if applied to the tongue, will give a taste like that of putrid eggs, arising from the formation of sulphuretted hydrogen. It consists of one eq. of acid 40, and one of baryta 76.7 = 116.7. This salt, on account of its great insolubility, is not poisonous. Ground to fine powder, it is sometimes mixed with white lead, but impairs the quality of that pigment. The artificial sulphate of baryta, under the name of permanent white or blanc-fix, is much used in the arts as a water-colour. It is made from both the native sulphate and carbonate. It forms a dazzling white colour, unalterable by light, heat, air, or sulphuretted hydrogen. It is used by the manufacturers of paper hangings, and is mixed with other colours, the tone of which it does not impair.

SULPHATE OF NICKEL. Niccolii Sulphats. This salt is formed by dissolving carbonate of nickel in dilute sulphuric acid, concentrating the solution, and setting it aside to crystallize. The carbonate is procured by dissolving the impure arseniuret of nickel, sold under the name of speiss, coarsely powdered and mixed with half its weight of iron filings, in nitromuriatic acid. The solution is evaporated to dryness, and the residue treated with water, which takes up the impure chloride of nickel, and leaves the arsenic in the form of the insoluble arseniate of iron. The liquid is then acidulated with muriatic acid, treated with sulphuretted hydrogen in excess, which precipitates the copper, and, after filtration, boiled with a little nitric acid to sesquisoioxide any remaining iron. The cold liquid, largely diluted with water, is next treated with a solution of bicarbonate of soda, gradually added, which throws down the iron in the state of sesquisoioxide. Lastly, the filtered solution, containing the chloride of nickel nearly pure, is boiled with carbonate of soda, which, by double decomposition, throws down a pale-green precipitate of carbonate of nickel. Sulphate of nickel is in the form of emerald-green crystals, efflorescent in the air, soluble in three parts of cold water, but insoluble in alcohol and ether. It has a sweet, astringent taste. When crystallized in rhombic prisms, it consists of one eq. of sulphuric acid 40, one of protoxide of nickel 97.5, and seven of water 63 = 140 S. (NiO.SO₄ + 7HO.)

Prof. Simpson, of Edinburgh, has made some therapeutic trials with this salt, and found it to act as a gentle tonic, like the preparations of iron and quinia, yet somewhat differently. He used it successfully in a case of severe and obstinate periodic headache. The
dose is from half a grain to a grain three times a day, given in the form of pill, or of simple solution. In large doses it is liable to produce nausea and vomiting, especially on an empty stomach. (See Braithwaite's Retrospect, xxvii. 446.)

**B.**

**SULPHOCYANIDE OF POTASSIUM. Potassii Sulphocyanidum.** This salt is prepared by fusing in an iron vessel, at a low red heat, a mixture of two parts of dried ferrocyanide of potassium, and one part of flowers of sulphur. The mass, when cold, is dissolved in boiling water; and, to decompose some sulphocyanide of iron, the solution is treated with carbonate of potassa, which throws down the iron as a carbonate, and gives rise to the formation of a fresh portion of sulphocyanide of potassium. The whole is then boiled for a quarter of an hour, filtered to separate the precipitated iron, and evaporated that crystals may form. These are purified from carbonate of potassa by being dissolved in alcohol, which takes up the sulphocyanide and leaves the carbonate. The alcoholic solution is then allowed to crystallize. Sulphocyanide of potassium is in long, striated, anhydrous prisms, deliquescent in a moist atmosphere, very soluble in alcohol, and having a cooling, somewhat biting taste. It has been proposed as a medicine by Soemmering, as a substitute for hydrocyanic acid and cyanide of potassium, on the ground that it possesses the same therapeutic properties, without their inconveniences.

**B.**

**SULPHURET OF CALCIUM. Calcii Sulphuretum. Hydrosulphate of Lime.** This compound is formed by passing sulphuretted hydrogen, so long as it is absorbed, through water holding lime in suspension. It is in the form of a paste of a greenish-gray colour, and exhaling a strong odour of sulphuretted hydrogen. It is used as a depilatory, and is applied in a layer on the part which is to be deprived of hair. At the end of fifteen minutes it is removed with a wet sponge, which at the same time detaches the hairs. On account of this preparation giving out sulphuretted hydrogen, it must not be applied near the mouth or nose. An impure aqueous solution of sulphuret of calcium, necessarily containing hypo-sulphite of lime from the manner of its preparation, is used with great success, in Belgium, in itch, the cure of which it effects in a few hours. It is made by boiling together one part of sublimed sulphur, two of lime, and ten of water. The liquid is allowed to cool, and the clear part poured off, and kept in well-stopped bottles. For an explanation of the reaction which takes place, see Sulphur Precipitatum, page 1359. The patient, after having been well washed with soap and tepid water in a bath, is rubbed over with the liquid, which is allowed to dry on the skin for a quarter of an hour. A second bath is then taken, which completes the cure. The preparation, when it dries, leaves on the skin a thin layer of the sulphur compound, which destroys the itch insect and its eggs.

**B.**

**SULPHURET OF IRON. Ferri Sulphuretum.** Ed., Dub. This former official of the Edinburgh and Dublin Colleges, merits and ought to have a place in the Pharmacopoeias, as the source whence sulphuretted hydrogen, so much used both in the preparation and testing of medicines, is most conveniently obtained. The following is the late Dublin process for preparing it. "Take of rods of Iron, of the size employed in the manufacture of nails, any convenient number. Having raised them to a strong red or white heat, apply them in succession by their heated extremities to sticks of Sulphur, operating so that the melted Sulphuret, as it is formed, may drop into a stone cistern filled with water, and be thus protected from oxidation. The water being poured off, let the product be separated from the Sulphur with which it is mixed, and, when dried, let it be enclosed in a well-stopped bottle." (Dub.) Iron and sulphur form a number of sulphures, among which the most important are the protosulphuret and sesquisulphuret, corresponding with the protoxide and sesquioxide of iron, the bisulphuret or cubic pyrites, and magnetic pyrites, which is a compound of five eqs. of protosulphuret, and one of bisulphuret. When the sulphuret is obtained by the application of solid sulphur to white-hot iron, the product corresponds with magnetic pyrites; but, when procured by heating flowers of sulphur with an excess of iron filings, as directed in a former Edinburgh process, a protosulphuret is formed mixed with metallic iron. When sulphur is applied to white-hot iron over water, the metal appears to become hotter, burns with scintillations in the vapour of the sulphur, and forms instantly the sulphuret, which, being comparatively fusible, melts into globules, and drops into the water, which serves to extinguish them.

The sulphuret of iron, made according to the late Dublin process, has a yellowish colour and the metallic lustre. When obtained over water it is in the form of brownish-yellow globules, having a somewhat crystalline texture. When pure it furnishes a yellow powder, and dissolves in dilute sulphuric or muriatic acid without leaving a residue of sulphur, and with the production of hydro sulphuric acid gas (sulphuretted hydrogen), free from admixture of hydrogen. It is not entirely soluble in dilute sulphuric acid, a portion of uncombined sulphur being left. The fused globules have the composition 5FeS + FeS₂, or, according to some, 5FeS + Fe₂S₅. This sulphuret is employed solely as a pharmaceutical agent for the production of hydro sulphuric acid. It yields this gas by reaction with dilute sulphuric acid. Water is decomposed; its hydrogen combines with the sulphur to form hydro sulphuric acid, while the oxygen converts the iron into protoxide, with which the sulphuric acid unites.
Hydrosulphuric acid is a colourless gas, having a smell like that of putrid eggs. Its sp. gr. is 1.1752. It saturates bases, with which it forms salts called hydrosulphates, sulphohydrides, or hydrosulphures. It consists of one eq. of sulphur 16, and one of hydrogen 1:17.

B.

SUMBUL. | Jatamansi. Musk-root. Under the name of sumbul or jatamansi, a root has long been used in India, Persia, and other parts of the East, as a perfume, an incense in religious ceremonies, and medicinally. It is the product of an unknown plant, supposed to be umbelliferous, and, from the character of the root, to grow in low wet places. The plant is said to inhabit no part of British India, but the regions to the north and east of it, as Nepaul, Booan, Buchara, &c. The root is taken northward to Russia, and reaches the rest of Europe through St. Petersburg. The physicians of Moscow and St. Petersburg were the first to employ it on the continent of Europe. Dr. Granville first introduced it to the notice of the profession in Great Britain and this country. It has recently also been imported into England from India, whither it was brought from a great distance in the interior.

The medicine comes in transverse sections, from two to four inches in diameter, and from an inch to an inch and a half in length, with a dusky, light-brown, wrinkled epidermis, and an interior porous structure, consisting of coarse, irregular, easily separable fibres. The fresh cut surface of a transverse section presents, within the epidermis, an exterior white and spotted layer, and an inner yellow substance which forms the greater part of the root. Examined by means of a microscope, it exhibits translucent points which probably represent starch granules. Sumbul has a strong odour, very much resembling that of rose oil, which it retains even when long kept. The taste, at first feebly sweetish, becomes after a time bitter and balsamic, but not disagreeable; and a strong aroma is developed under mastication, diffusing itself with a sensation of warmth through the mouth and throat, and rendering the breath fragrant. This effect, however, is much diminished by time. That brought from India differs somewhat from the Russian, being of closer texture, more dense and firm, and of a reddish tint. (Am. Journ. Pharm., xxiv. 174, from Pharm. Journ.)

The root has been analyzed by Reinsch and other German chemists, and found to contain volatile oil, two balsamic resins, one soluble in alcohol, the other in ether, wax, gum, starch, a bitter substance soluble in water and alcohol, a crystallizable acid, which Reinsch proposes to call sumbulic acid, and saline matter. The musk-like odour seems to be connected with the balsamic resins, and probably depends on some principle associated with them not yet isolated. The volatile oil yielded by distillation has a taste like that of peppermint.

The virtues of the drug appear to be those of a nervous stimulant. It is used by the Russian physicians in low fevers of a typhous character, and in asthenic cases of dysentery and diarrhoea. It has also been employed by them with asserted success in malignant cholera. The authors, on the occasion of a visit in the summer of 1853 to St. Petersburg, were informed by Dr. Thielmann, physician to the Hospital of St. Peter and St. Paul, that he depended mainly on this remedy in the treatment of delirium tremens, having found it superior in its composing influence over that complaint even to opium. Dr. Granville recommends it in gastric spasms, hysteria, chlorosis, amenorrhœa, dysmenorrhœa, palsy of the limbs, epilepsy, and other nervous disorders. It is given in substance, infusion, decoction, and alcoholic and ethereal tincture. There seems to be no great precision in relation to the dose; but it is inferrable, from the accounts of the drug, that it may be used very much as we use valerian. The facts above stated are taken chiefly from a pamphlet by Dr. Granville, published in London, A.D. 1850.

Dr. Murawieff, of Russia, prepares the resin, which he considers as the active principle, by macerating the root first in water, and then in a solution of carbonate of soda, washing it well with cold water, drying it, treating it with alcohol, filtering the tincture, adding a little lime and again filtering, separating the lime by sulphuric acid, agitating with animal charcoal, again filtering, distilling off nearly all the alcohol, mixing the residuum with water, driving off the remaining alcohol, and, finally, washing the precipitate with cold water, and drying it. The resin thus obtained is whitish, translucent, softening between the fingers, combustible without residue, of an acid taste, and an aromatic smell, like that of the root. Dr. Murawieff gives it in the dose of a grain or two, in the form of pill, three or four times a day, with or without opium, and has found it useful in chronic bronchitis and pneumonia slow of resolution, in the moist asthma of oid, anemic, and seborrhœic patients, in atonic dysentery, leucorrhœa, hypochondriasis, and hysteria. (Dub. Quart. Journ., Feb. 1866, p. 252, from Med. Zeit. Russland.) Prof. Procter has published a formula for a fluid extract, of which the dose is from 15 minims to a fluid dram. (Am. Journ. Pharm., xxvii. 293.)

W.

SWIETENIA FEBRIFUGA. A large tree growing in the East Indies. The bark is the part employed. It is smooth and red internally, rough and gray on the outer surface, of a feeble aromatic odour, and an astringent bitter taste. Water extracts its virtues by infusion or decoction. It is said to have been much used in India as a substitute for Peruvian bark, to which it is somewhat analogous in medical properties. The dose of the powder is from thirty grains to half a dram. The watery extract has the virtues of the bark.

The Swietenia Mahogoni, or mahogany tree, which grows in the West Indies and other parts
of tropical America, has also a bitter astringent bark, which resembles that of S. febrifuga in virtues as well as in sensible properties. The wood of this tree is the mahogany so much used in ornamental wood-work. The bark of S. senegalensis is used on the coast of Africa in the cure of intermittents; and M. Caventou has extracted an alkaloid from it, which has been suggested as a cheap substitute for quinia. (See Am. Journ. of Med. Sci., N. S., xx. 168.)

SYMPHYTUM OFFICINALE. Comfrey. A perennial European plant, cultivated in our gardens for medical use. Its root, which is the part used, is spindle-shaped, branched, often more than an inch thick and a foot long, externally smooth and blackish, internally white, fleshy, and juicy. By drying it becomes wrinkled, of a firm horny consistence, and of a dark colour within. It is almost inodorous, and has a mucilaginous, feebly astringent taste. Among its constituents are mucilage in great abundance, and a small quantity of tannin. It was formerly highly esteemed as a vulnerary, but has lost its credit in this respect. Its virtues are chiefly those of a demulcent, and it may be advantageously used for all the purposes to which the marshmallow is applied. It is a very common ingredient in the domestic cough mixtures, employed in chronic catarrh, consumption, and other pectoral affections. The most convenient form of administration is that of decoction, which may be made either from the fresh or dried root. According to Lewis, comfrey root yields to water a larger proportion of mucilage than the root of Althea.

SYRINGA VULGARIS. Common Lilac. The leaves and fruit of this common garden plant have a bitter and somewhat acid taste, and have been used as a tonic and febrifuge. In some parts of France, they are said to be employed habitually by the country people in the cure of intermittent fever: and they were recommended by Cruveilhier in the treatment of that complaint. The fruit was examined by MM. Petroz and Robinet, who found it sweet and a bitter principle. The latter was afterwards obtained pure by M. Meillet, who gave it the name of lilacin. The green capsules, which yield it in largest proportion, are boiled in water, the decoction is concentrated, subacetate of lead is added, the liquor is evaporated to the consistence of syrup, magnesia is added in excess, and the whole is evaporated to dryness. The residuum is powdered, digested in water at 90° or 100°, and then treated with boiling alcohol and animal charcoal. The alcoholic solution, being filtered and concentrated, yields lilacin upon cooling. This principle, though not alkaline, is thought by M. Meillet to exist in the fruit combined with malic acid. It is crystallizable, bitter, and insoluble in water. (Am. Journ. of Pharm., xiv. 139, from Journ. de Pharm.)

TACAMAHAC. Tacamahaca. The resinous substance, commonly known by this name, is supposed to be derived from the Fagara octandra of Linn. (Elaphrium tomentosum, Jacq., Amyris tomentosa, Spreng.), a tree of considerable size, growing in the island of Curacao, and in Venezuela. The juice exudes spontaneously, and hardens on exposure. As brought into the market, it is in irregularly shaped pieces of various sizes, some not larger than a mustard seed, others as much as an inch or two inches in diameter. The colour is usually light-yellowish or reddish-brown; but in the larger masses is more or less diversified. The pieces are in general translucent, though frequently covered with powder upon their surface, so as to render them apparently opaque. They are heavier than water, brittle, and pulverizable, yielding a pale-yellow powder. Their odour is resinous and agreeable, their taste bitter, balsamic, and somewhat acid. Exposed to heat they melt and exhal a stronger odour. Tacamahac is partially soluble in alcohol, and completely so in ether and the fixed oils. It consists of resin with a little volatile oil.

Another variety is obtained from the East Indies, and called tacamahaca orientale, or tacamahaca in tectis. It is supposed to be derived from the Calophyllum inophyllum, and comes into the market in gourd-shells covered with rush leaves. It is of a pale-yellow colour inclining to green, slightly translucent, soft, and adhesive, of an agreeable odour, and an aromatic bitterish taste. It is at present very rare in commerce. The tree which yields this resin produces a drupe, about as large as a plum, from the seeds of which 50 per cent. of a greenish-yellow fixed oil is obtained by expression, used in India for lamps, and as a local application in the itch. (Journ. de Pharm., Juillet, 1861. p. 23.)

Guibourt describes several other varieties of tacamahac, which, however, are little known. Among them is a soft, adhesive, dark-green resin, said to be procured from the Calophyllum tacamahaca, growing in the islands of Bourbon and Madagascar.

Tacamahac was formerly highly esteemed as an internal remedy, but is now employed medicinally only in the composition of ointments and plasters, and little even for this purpose. Its properties are analogous to those of the turpentines. It is sometimes used as incense.

TANNATE OF ALUMINA. Alumine Tannae. Mr. Rogers Harrison, of London, has employed an aqueous solution of a substance which he calls by this name, as an injection in gonorrhoea, after the acute symptoms have passed. He makes it of such a strength as to produce smarting. The substance is described to be in crystals, about the size of those of coarse sugar, of a dirty-yellowish colour, and readily soluble in hot water.
Tannate B. B. petals; Linnfius has white with feet most green a to its knee-joint. It is inclined to think that it was a mixture of tannic acid and alum. (Am. Journ. of Pharm., Jan. 1853, p. 25.)

TANNATE OF IRON. Ferri Tannas. This salt is prepared by dissolving 44 parts of precipitated subcarbonate of iron, moderately dried, in a boiling solution of 9 parts of pure tannic acid, evaporating the solution at the temperature of 170°, in a porcelain vessel, until it becomes thick, pouring it out on a glass or porcelain plate, and drying it with a gentle heat. As thus obtained, tannate of iron is in flat pieces, of a crimson colour, without taste, and insoluble in water. It acts as an astringent and tonic, and may be given in chlorosis, in the dose of from eight to thirty grains, in the course of a day, made into pills. Ink is an aqueous solution of the tanno-gallate of iron, and probably possesses similar medical properties. It is a popular application to ringworm.

TANNATE OF LEAD. Plumbi Tannas. This is obtained by precipitating a concentrated infusion of oak bark with acetate of lead, added drop by drop. It has been used as an external application with success by Dr. Fontanetti in two cases of white swelling of the knee-joint. He employed it at first mixed with a third of its weight of lard, and afterwards pure, the fresh precipitate admitting of application as an ointment. Antienrich recommends it as a dressing to gangrenous ulcers; and it is probably peculiarly efficacious in bed-sores. With this intention, the precipitate, either uncombined, or mixed in its dry state with simple ointment in the proportion of two drachms to the ounce, may be spread on linen, and applied to the sore. The preparation here described is a bitannate. Other tannates of lead exist.

TARTRATE OF SODA. Soda Tartras. This salt, in crystals, has been recommended by M. Delieux as an agreeable purgative, almost without taste, and acting with power equal to that of the sulphate of magnesia, in the dose of ten drachms. The soda powders, so much used in the United States, form an extemperaneous tartrate of soda, somewhat aërated with carbonic acid. (See page 1306.)

TEA. The plant which furnishes tea—Thea Chinensis—is an evergreen shrub, belonging to the class and order Monadelphia Polyandria of the sexual system (Polyandria Monogynia, Linn.), and to the natural order Ternstroemiaceae. It is usually from four to eight feet high, though capable, in a favourable situation, of attaining the height of thirty feet. It has numerous alternate branches, furnished with elliptical-oblong or lanceolate, pointed leaves, which are serrate except at the base, smooth on both sides, green, shining, marked with one rib and many transverse veins, and supported alternately upon short footstalks. They are two or three inches long, and from half an inch to an inch in breadth. The flowers are either solitary, or supported, two or three together, at the axils of the leaves. They are often considerable size, not unlike those of the myrtle in appearance, consisting of a short green calyx with five or six lobes, of a corolla with from four to nine large unequal snow-white petals, of numerous stamens with yellow anthers and connected at their base, and of a pistil with a three-parted style. The fruit is a three-celled and three-seeded capsule. It has not been certainly determined whether more than one species of the tea-plant exists. Linneus admitted two species—T. Bohea and T. viridis—differing in the number of their petals; but this ground of distinction is untenable, as the petals are known to vary very much in the same plant. Hayne makes three species—T. stricta, T. Boheu, and T. viridis—which are distinguished severally by the shape of their leaves and fruit, and the direction of the footstalk. De Candolle admits but one species, with two varieties—the viridis or green tea, with "lanceolate flat leaves, three times as long as they are broad," and the Bohea, with "elliptical oblong, subrugose leaves, twice as long as broad." Lindley recognises the two Linnean species, distinguishing them by the leaves, which in T. viridis are acuminate, and emarginate at the apex, and in T. Bohea are smaller, flatter, darker green, with small serratures, and terminate gradually in a point, but are not at all acuminate or emarginate. (Flora Medica, 120.)

The tea-plant is a native of China and Japan, and is cultivated in both countries, but most abundantly in the former. In Japan it forms hedgerows around the rice and cornfields; in China, whence immense quantities of tea are exported, whole fields are devoted to its culture. It is propagated from the seeds, which are planted in holes at certain distances, six or eight seeds being placed in each hole, in order to ensure the growth of one. In three years the plant yields leaves for collection, and in six attains the height of a man. When from seven to ten years old it is cut down, in order that the numerous shoots which issue from the stump may afford a large product of leaves. These are picked separately by the hand. Three harvests, according to Kömpfer, are usually made during the year; the first at the end of February, the second at the beginning of April, and the third in June. As the youngest leaves are the best, the product of the first collection is most valuable, while that of the third, consisting of the oldest leaves, is comparatively little
Tea. Sometimes only one or two harvests are made; but care is always taken to
assort the leaves according to their age; and thus originate numerous commercial varieti
ties of tea. The character of the plant, dependent upon the soil, situation, climate, and
culture, has also a great influence upon the value of the leaves. It is said that the best
tea is procured from the shrubs which grow upon the sides of steep hills with a southern
exposure. Though the plant grows both about Pekin in the north and Canton in the south
of China, it is said to attain greater perfection in the intermediate country, in the neigh-
bourhood of Nankin, for instance, where the climate is neither so cold as in the first-men-
tioned vicinity, nor so hot as in the second. Some of the commercial varieties have their
origin in this cause; and it is highly probable, though the fact has not been certainly proved,
that difference in species may be another source of diversity. After having been gathered,
the leaves are dried by artificial heat in shallow iron pans, from which they are removed
while still hot, and rolled with the fingers, or in the palm of the hand, so as to be brought
into the form in which they are found in commerce. The odour of the tea leaves themselves
is very slight; and it is customary to mix with them the flowers of certain aromatic plants,
as those of the orange, different species of jasmine, the rose, Olea fragrans, and Camellia
Sasanqua, in order to render them pleasant to the smell. The flowers are afterwards separ-
ated by sifting or otherwise. (See Pharm. Journ., xv. 112.) The cultivation of tea has
been successfully introduced into Brazil, and into the British possessions in India. In
1861, about 20,000 acres of land were under cultivation in Assam, and are said to have
yielded 1,705,130 pounds of tea in that year. (Galligant's Messenger, Jan. 20th, 1862, from
the London Times.) Mrs. Ida Pfeiffer states, in her Second Journey round the World (Am.
ed., 1857, p. 127), that tea cultivated in Java is occasionally sent to Europe. Attempts have
been made, under the auspices of the Government, to introduce the tea-culture into the
U. States. Large numbers of the seeds were, through arrangements made by the Patent
Office, imported from China, and, having been planted in the propagating garden at Wash-
ington, germinated satisfactorily. At the time of publication of the Patent Office report,
in 1859, the young plants continued to flourish, and there was every reason to hope that
the experiment would eventuate successfully.

Tea is brought to this country from Canton and other ports of China. Numerous varieties
exist in commerce, differing in the shape communicated by rolling, in colour, in flavour, or
in strength; but they may all be arranged in the two divisions of green and black teas, which,
at least in their extremes, differ so much in properties, that it is difficult to conceive that
they are derived from the same species.

Properties. Green tea is characterized by a dark-green colour, sometimes inclining more
or less to blue or brown. It has a peculiar, refreshing, somewhat aromatic odour, and an
astringent, slightly pungent, and agreeably bitterish taste. Its infusion has a pale green-
ish-yellow colour, with the odour and taste of the leaves. According to Mr. Warington, who
examined numerous varieties of tea carefully both by the microscope and chemical tests,
many of the green teas imported into Great Britain owe their colour to a powdery coating,
consisting of sulphate of lime and Prussian blue; others to a mixture of these with a yel-
lowish vegetable substance; and others, again, to sulphate of lime alone. (Pharm. Journ.,
iv. 37.) Black tea is distinguished by a dark-brown colour. It is usually less firmly rolled,
and lighter than the green, and contains the petioles of the plant mingled with the leaves.
Its odour is fainter, and of a somewhat different character, though still fragrant. Its taste,
like that of green tea, is astringent and bitterish; but is less pungent, and to many persons
less agreeable. To hot water it imparts a brown colour, with its sensible properties of taste
and smell. These vary exceedingly in degree in the different varieties; and some black
 teas are almost wholly destitute of aromatic or agreeable flavour. According to Mr. War-
ington, the difference between green and black tea, in reference to their chemical and
physical condition, arises from a kind of fermentation which the latter is made to undergo,
before being roasted. (Ibid. p. 618.) A sophisticated tea is largely exported from China,
consisting of powdered tea mixed with sand and other earth, and agglutinated with gum;
that which is to pass for black being coloured with plumago, and the green with the coa-
ting above referred to. On analysis, these teas were found to afford from 35 to 45 per cent.
of ashes, while the genuine yields only 5 per cent. They may be detected by not unfolding
when steeped in boiling water. (Ibid.)

Analyzed by G. J. Mulder, 100 parts of green Chinese tea afforded 0·79 of volatile oil,
2·22 of chlorophyll, 0·28 of wax, 2·22 of resin, 8·56 of gum, 17·80 of tannic acid of the
variety contained in galls, 0·48 of thein (cafein), 22·80 of extractive, traces of apothemne,
23·60 of muriatic extract, 3·00 of albumen, 17·68 of lignin, and 5·56 of salts. The mu-
riatic extract was the matter taken up by diluted muriatic acid from tea, previously ex-
hausted successively by ether, alcohol, and water, and consisted of artificial tannin. The
same chemist obtained from 100 parts of black Chinese tea 0·60 of volatile oil, 1·84 of
chlorophyll, 3·64 of resin, 7·28 of gum, 12·88 of tannic acid, 0·46 of thein (cafein), 19·88
of extractive, 1·48 of apothemne, 19·12 of muriatic extract, 2·80 of albumen, 28·32 of lignin,
and 5·24 of salts. (Annal. der Pharm., xxviii. 317.) Dr. Kochleder has found also a peculiar
acids, which he calls bohec acid. According to Stenhouse, the tannin of tea, though always accompanied with a little gallic acid, differs essentially from that of galls; not being like it a glucoside, but yielding, under the influence of sulphuric acid, a dark-brown substance, almost insoluble in water. (See Am. Journ. of Pharm., May, 1802, p. 254.) M. Eug. Peligot obtained a much larger proportion of thee or caffein than was found by Mulder, the lowest quantity from green tea being 2.4 per cent., and the highest 4.1 per cent.; but even this quantity is too small to represent all the nitrogen contained in tea. (Journ. de Pharm., 3e sér., iv. 224.) M. Puccetti found about twice as much in black as in green tea. (Am. Journ. of Pharm., xxviii. 224.) The volatile oil is probably one of the principles upon which the effects of tea upon the nervous system depend. Hence old teas are less energetic than those recently imported; and it is said that the fresh leaves have often produced dangerous effects in China. Nevertheless, the tannic acid is not without influence upon the system; and it is not improbable that both the extractive and their contribute to the peculiar influence of this valuable product. Of these active ingredients, the volatile oil, tannic acid, and extractive are found most largely, according to the analysis of Mulder, in the green tea. Their is a crystallizable principle discovered by Oudry. It was afterwards proved by Jobst to have the same composition as caffein, and is now generally considered as in all respects identical with that principle. It is also said to exist in the leaves of the Illex Paraguaiensis or Paraguayan tea, and in the seeds of Paullinia sorbile. (See Coffee, Ilex, and Paullinia.) According to Mulder, their exists in tea combined with tannic acid. Peligot obtained it by adding to a hot infusion of tea, first subacetate of lead, and then ammonia, filtering the liquid, passing sulphuretted hydrogen through it, again filtering, and evaporating with a moderate heat. On cooling, the liquid deposited them abundantly, and yielded an additional quantity by a careful evaporation. (Journ. de Pharm., 3e sér., iv. 224.) It may be cheaply prepared by putting some old spoiled tea in an iron pot covered with filtering paper, enclosing the whole in a cylindrical paper cap, and cautiously applying heat. Their rises in vapour, and condenses on the paper. (See Chem. Gaz., No. 178, p. 119.) Their has a feebly bitter taste; is, in the state of crystals, dissolved by 93 parts of water, 158 of alcohol, and 298 of ether; melts at about 350° C., and at 725° sublimes in white vapours, which condense in minute needlles. From its watery solution few reagents precipitate it. Infusion of galls causes a de- posit of tannate of their, which is again, however, dissolved by heating the water.

Medical Properties and Uses. Tea is astringent and gently excitant, and in its finer varieties exerts a decided influence over the nervous system, evinced by the feelings of comfort and even exhilaration which it produces, and the unnatural wakefulness to which it gives rise, when taken in unusual quantities, or by those unaccustomed to its use. Its properties, however, are not of so decided a character as to render it capable of very extensive application as a medicine; and its almost exclusive use is as a grateful beverage at the evening and morning meals. Taken moderately, and by healthy individuals, it may be considered as perfectly harmless; but long continued, in excessive quantity, it is capable of inducing unpleasant nervous and dyspeptic symptoms, the necessary consequences of over-excitement of the brain and stomach. Green tea is decidedly more injurious in these respects than black, and should be avoided by dyspeptic individuals, and injurious whose nervous systems are peculiarly excitable. As a medicine, tea may sometimes be given advantageously in diarrhoea; and a strong infusion will often be found to relieve nervous headache. The mode of preparing it for use is too well known to require description. An extract is made from it in China, which is said to be useful in fevers. Though the effects of tea and coffee upon the system are probably in part owing to the their or caffein they contain, there must be some other active ingredient; as the effects produced by different varieties are not proportionate to the amount of that principle contained in them. Thus coffee, which exerts a more powerful influence upon the system than tea, in any of its varieties, contains less caffein. W.

TELLURIUM. Several of the combinations of this metal have been tried on the living organism by M. Hansen. Five grains of the tellureo of potassa, given to dogs, produced suffocation and vomiting, and the garlic-like odour of telluriun in the breath. The same salt, tried upon himself for seven successive days, in a dose daily of half a grain, afterwards increased to a grain, caused drowsiness at first, followed, after the seventh day, by a sense of oppression in the cardiac region, nausea, an increased flow of saliva, and loss of appetite. The breath had a garlic like odour throughout the experiment. (Chem. Gaz., March 1, 1864, p. 90.) Prof. Simpson, of Edinburgh, relates the case of a student, who inadvertently took a dose of telluriun, and exhaled so persistent an odour that he had to sit apart from his fellow students. (See Am. Journ. of Med. Sci., April, 1855, p. 406.) This disagreeable effect of telluriun precludes its employment in medicine.

TEPHROSIA VIRGINIANA. Turkey Pea. Goat's Rue. Several species of Tephrosia are employed in different parts of the world, though unknown in general commerce. They are leguminous plants, shrubby or herbaceous, with leaves unequally pinnate, and flowers in axillary or terminal racemes. They are generally possessed of cathartic properties; their leaves or roots being employed. Tephrosia Virginiana grows in most parts of the United States. It is a foot or two high, with pubescent stems and leaves, and handsome termina...
PART III. Teucrium Chamædrys.—Thlapsus Bursa Pastoris. 1613

flowers. (See Griffith's Med. Bot., p. 237.) The roots, which are slender, long, and matted, are tonic and aperient, and are said to have been used by the Indians as a vermicife, given in the form of decoction. Dr. B. O. Jones, of Atlanta, Geo., has used the plant with advantage, as a mild stimulating tonic and laxative, having a tendency to increase most of the secretions, and has found it specially useful in typhoid fever. He prepares it by boiling eight ounces of the plant with two ounces of Rumex acutus in four quarts of water to a quart, and straining; adding, when the preparation is to be kept, an equal bulk of diluted alcohol or brandy, and half its weight of sugar, and macerating for several days. The dose is one or two tablespoonsfuls. (Am. Journ. of Pharm., xxviii. 218.) W.

TEUCRIUM CHAMÆDRYS. Germander. Chamædrys. A small, didynamous, labiate, perennial European plant, the leaves and tops of which have an agreeable aromatic odour, diminished by drying, and a bitter, somewhat astringent, aromatic, durable taste. They have been employed as a mild corroborant, in uterine, rheumatic, gouty, and scrophulous affections, and intermittent fevers; but are at present little used, and never in this country. Germander was an ingredient in the Portland powder, noted as a remedy in gout. This powder, according to the original prescription, consisted of equal parts of the roots of Aristolochia rotunda and Gnidium lutea, of the tops and leaves of Teucrium Chamædrys and Erhythraea Centaurium, and of the leaves of Ajuga Chammyptis, or ground pine. The dose was a drachm every morning before breakfast, for three months, then two scruples for three months, afterwards half a drachm for six months, and finally half a drachm every other day for a year. (Parr.) Two other species of Teucrium have been used in medicine;—T. Marum, cat-thyme, or Syrian herb mosticth, indigenous in the south of Europe, and T. Scorridum, or water germander, growing in the higher latitudes of the same continent. The former is a warm, stimulating, aromatic bitter, and has been recommended in hysteria, amennorrhœa, and nervous debility; the latter has the odour of garlic, and a bitter, somewhat pungent taste, and was formerly highly esteemed as a corroborant in low forms of disease; but neither of them is now much employed. T. Marum, however, has been revived somewhat of late; having been given successfully, by Dr. Lucanus, in pertussis and other cases of spasmodic cough, in the forms of syrup and confection. (Revue Pharmaceut., 1858, p. 32.) This species also acts as an erthine, and was formerly an ingredient in the Pulvis Asari Compositus. The dose of either of the three species is about half a drachm. A plant said to have been used advantageously in choleræ in the Levant, a specimen of which was sent to Paris, proved to be Teucrium Polium. (Journ. de Pharm., xxv. 352.) W.

THALLIUM. This is one of the metals recently discovered by means of the spectrum analysis, and has been found to prevail widely in nature, and to yield itself readily to chemical agencies. The point about it principally interesting to the physician at present is, that it has been ascertained to act energetically as a poison. M. Laury, having experienced, while making chemical investigations in reference to thallium, extreme general lassitude, with pains in the lower extremities, was disposed to consider these symptoms as the result of a poisonous influence of the metal. To determine the point, he dissolved 75 grains of sulphate of thallium in some milk, intending to try its effects on a couple of puppies, which, however, after tasting it, refused to swallow more. Accidentally it was placed where other animals had access to it; and the consequences were that the milk disappeared, and a middle-sized dog, a hen, and six ducks died from having drank it. There was no vomiting or purging, but violent intestinal pains, and spasm of the posterior limbs, followed by paralysis; and this last seemed to be the most characteristic effect of the poison. Death took place in two or three days; and, what is of much importance, the two puppies which had only tasted of the milk, were seized with similar symptoms, and died at the end of four days. The poison, therefore, must be very energetic; and a circumstance worthy of remark in relation to it is, that, even in a fatal dose, it may produce no sensible effect for a considerable time. M. Laury afterwards gave a grain and a half to a puppy, which died in forty hours. There seems to be a remarkable coincidence between the poisonous effects of thallium and those of lead. Connected with its deleterious action, it is an interesting circumstance that thallium is not frequently associated with metals used in medicine, as with copper and bismuth for example. Spectrum analysis affords an easy method of detecting the poison. M. Laury readily recognised it in the tissues of animals which perished with it, by subjecting small pieces to examination in the spectroscope. A sharply defined green line in the spectrum gave undoubted evidence of the presence of the poison. (Journ. de Pharm., Oct. 1863, p. 285.) W.

THILAPSUS BURSA PASTORIS. Shepherd's Purse. Thilapsus is a genus of Cruciferous plants, of which several species grow in this country. In Europe, the T. bursa pastoris is a very common plant, growing everywhere upon walls, by the road sides, in gardens, &c., and flowering nearly all the year. Like others of the same natural family, it yields by contact with water a volatile oil, which may be obtained by distillation. The plant is bitter and pungent, and is supposed to possess astringent properties; being employed with asserted advantage in hæmaturia and other hemorrhages. It is also thought to be specially antiscor-
Thuya Occidentalis.—

**Tin.**

PART III.

TIN. *Stannum.* This was recognised in the late Ed. and Dub. Pharmacopoeias, and in the U.S. of 1850; but is no longer official. It has, however, too long ranked among recognised remedies to be passed without notice. Tin is one of the metals which have been known from the earliest ages. It exists generally as an oxide (*tin stone and wood tin*), rarely as a sulphuret (*tin pyrites*), and is by no means generally diffused. It is found in England, Spain, Germany, Bohemia, and Hungary, in Europe; in the island of Banca and the Peninsula of Malacca, in Asia; and in Chili and Mexico. Tin mines are particularly abundant and rich in the Tenasserim provinces of British India. (*Dr. Royle.*) A valuable tin ore has been discovered in the United States, at Jackson, New Hampshire. The Cornwall mines are the most productive, but those of Asia furnish the purest tin. The metal is extracted from the native oxide. When this occurs in its pure state, in detached roundish grains, called *stream tin,* the reduction is effected by heating with charcoal. When the common oxide, called *mine tin,* is melted, it requires to be freed, by pounding and washing, from the adhering gangue; after which it is roasted to drive off sulphur, arsenic, and antimony, and finally reduced in furnaces by means of stone coal. The metal, as thus obtained, is called *block tin,* and is not pure. The purest kind of tin, known in commerce, is called *grain tin.*

**Properties.** Tin is a malleable, rather soft metal, of a silver-white colour. It may be beaten out into thin leaves, called *tin foil.* It undergoes a superficial tarnish in the air. Its taste is slight, and when rubbed it exhales a peculiar smell. Its ductility and tenacity are small; when bent to and fro, it emits a crackling noise, which is characteristic. Its sp. gr. is 7-29, melting point 442°, equivalent number 59, and symbol Sn. It forms three oxides, a protoxide, sesquioxide, and deutoxide. The *protoxide* is of a grayish-black colour. When perfectly pure it has, according to Dr. Roth, a red colour. The *sesquioxide* is gray. The *deutoxide* acts as an acid, and exists in two isomeric states, called *stannic* and *metastannic acid.* Stannic acid may be prepared by decomposing bichloride of tin with water. The metastannic acid is formed by acting on tin with nitric acid, which converts it into a white powder. The native crystallised oxide is metastannic acid. These acids, having the same composition, SnO₂, are perfectly distinct in chemical properties. The stannic acid is soluble, the metastannic insoluble in nitric acid and dilute sulphuric acids. One eq. of potassa requires for saturation one eq. of stannic acid, but five of metastannic acid. Hence the latter is sometimes represented by SnO₄²⁻.

The tin of commerce is often impure, being contaminated with other metals, introduced by fraud, or present in consequence of the mode of extraction from the ore. A high specific gravity is an indication of impurity. When its colour has a bluish or grayish cast, the presence of copper, lead, iron, or antimony, may be suspected. Arsenic renders it whiter, but...
at the same time harder; and lead, copper, and iron cause it to become brittle. Pure tin is converted by nitric acid into a white powder (metastannic acid), without being dissolved. Boiled with muriatic acid, it forms a solution which gives a white precipitate with ferrocyanide of potassium. A blue precipitate with this test indicates iron, a brown one copper, and a violet-blue one both iron and copper. If lead be present, a precipitate will be produced by sulphate of magnesia. The Malacca and Banca tin, and the English grain tin are the purest kinds found in commerce. Banca tin, from recent analyses by Mulder, appears to be particularly pure, containing only one-twenty-fifth of 1 per cent of foreign metals. Block tin and the metal obtained from Germany are always of inferior quality.

Uses. Tin enters into the composition of bronze, bell-metal, pewter, and plumber's solder. It is used also in making tin-plate, which is sheet-iron coated with tin, in silvering looking-glasses, and in forming the solution of bichloride of tin, a combination essential to the perfection of the scarlet dye. It is employed in fabricating various vessels and instruments, useful in domestic economy and the arts. Being unaffected by weak acids, it forms a good material for vessels intended for boiling operations in pharmacy. We are told that a false tin foil is considerably used at present, made by coating lead with tin, and then rolling it out into thin sheets. As tin foil is employed for enclosing medicinal powders, and in other ways is brought into contact with medicinal substances, care should be taken not to use this substituted preparation, lest the patient might be exposed to the poisonous action of lead.

Stannii Pudica. U. S. 1850. Powder of Tin. The following directions were given for preparing powder of tin in the U. S. Pharmacopoeia of 1850. "Take of Tin a convenient quantity. Melt it in an iron vessel over the fire, and, while it is cooling, stir it until it is reduced to a powder, which is to be passed through a sieve." U. S. Tin, being very fusible, is easily granulated by fusion, and subsequent agitation while solidifying. On a small scale, the granulation is most conveniently performed in a wooden box, the inside of which has been well rubbed with chalk. This should be afterwards washed away with water; and, as the granulated powder is of unequal fineness, the coarser particles must be separated by a sieve.

Medical Properties and Uses. Powder of tin is used exclusively as an anthelmintic, and is supposed to act by its mechanical properties. It is considered particularly adapted to the expulsion of Ascaris lumbricoides, and is also employed to expel the tapeworm. For internal exhibition it should be free from oxidation. The dose is half an ounce, mixed with molasses, given for several successive mornings, and then followed by a brisk cathartic. Dr. Alston was in the habit of administering larger doses for the expulsion of the tapeworm. He began by giving an ounce on an empty stomach, which was followed, for two successive days, by half an ounce each day, and finally by a brisk purge.

TONKA BEAN. The seed of Dipertiz odorata of Willd., the Cowmarouva odorata of Aublet, a large tree growing in Guiana. The fruit is an oblong-ovate pod, enclosing a single seed, from an inch to an inch and a half long, from two to four lines broad, usually somewhat compressed, with a dark-brown, wrinkled, shining, thin, and brittle skin, and a light-brown oily kernel. The bean has a strong, agreeable, aromatic odour, and a bitterish, aromatic taste. Its active constituent is a crystallizable, odorous substance, analogous to the volatile oils and camphor, and called coumarin by Guibourt. This substance is sometimes found in a crystalline state, between the two lobes of the kernel. It has been shown by M. Bleibtreu to be identical with the odorous principle of Asperula odorata, Trifolium melilotus, and Anthocyanthus odoratum. (See Chem. Gaz., Feb. 16, 1852, p. 61.) Mr. W. H. Lippitt, of Wilmington, N. C., having noticed a crystalline exudation upon the leaves of Liatris odorati- nina, growing in that neighbourhood, sent a specimen to Prof. Procter, of Philadelphia, who ascertained that it consisted of coumarin. According to Mr. Lippitt, this product of the Liatris was collected for the purpose of protecting woollens against moths. (Am. Journ. of Pharm., Nov. 1859, p. 566.) Dr. Gissmann obtains coumarin in the following manner. The beans, cut finely, are heated for a long time with an equal bulk of alcohol of 9 863, nearly to boiling; and, the tincture being decanted, the residue is treated in the same manner. The tinctures are mixed, the alcohol distilled off until turbidity appears, when four times the bulk of water is added, which precipitates coumarin and fatty matter. The precipitate is then heated to boiling, and the liquid passed through a moistened filter. The fatty matter remains on the filter, and the hot solution which passes deposits the coumarin on cooling. More may be obtained by concentrating the liquid, and may be purified by animal charcoal. One pound of the beans yielded 108 grains of coumarin. (Jbid., June 1, 1866, p. 211.) The tonka bean is used to flavour snuff, being either mixed with it in the state of powder, or put entire into the snuff-box.

TRIGONELLA FÆNUMGREGECUM. Fenugreek. An annual plant, growing spontaneously in different parts of the south of Europe, and cultivated in France and Germany for the sake of its seeds. These are oblong-cylindrical, somewhat compressed, obliquely truncated at each extremity, one or two lines in length, brownish yellow externally, yellow internally, and marked with an oblique furrow running half their length. They have a strong peculiar odour, and an oily, bitterish, farinaceous taste, and contain fixed and volatile oil, mucilage, bitter extractive, and a yellow colouring substance. An ounce of the seeds, boiled in a pint
of water, renders it thick and slimy. They yield the whole of their odour and taste to alcohol. Their virtues depend chiefly upon their oil and mucilage. On the continent of Europe they are employed in the preparation of emollient cataplasms and enemata, and enter into some official ointments and plasters. They are never used internally.

TRILLIUM. This is an indigenous genus of pretty, little, herbaceous plants, growing generally in woods and shady places. The roots are reputed to possess valuable remedial properties. They were employed by the aborigines, have been long used in domestic practice in some parts of the country, and were noticed as medicinal in Henry's Herbal, published in 1812. Dr. S. W. Williams published a paper upon them in the *New England Journ. of Med. and Surg.*, in the year 1820, and afterwards another in the *N. Y. Journ. of Med.* (viii. 94). The roots have a somewhat balsamic odour and taste, and produce, when chewed, a sense of heat and irritation, with an increased flow of saliva. A root received by Mr. E. S. Wayne, of Cincinnati, is described by him as an "oblong rhizome, with numerous rootlets attached to it, and of a yellowish-brown colour." Upon the removal of the epidermis, it is white and starchy, and gives a deep blue with tincture of iodine. Mr. Wayne found in the root an acrid principle, analogous to seneigin and saponin in the property of frothing with water; half a grain in two ounces of water being sufficient to show this property. He obtained it by treating the powdered root with alcohol by percolation, distilling off the alcohol and adding water as the alcohol escaped, separating an oleo-resin which floated on the surface of the remaining watery liquid, treating the latter with acetate and subacetate of lead so long as a precipitate was produced, filtering, separating the excess of lead by sulphuric acid, again filtering, and setting the clear liquid aside. In the following day a glutinous precipitate had formed, which, being collected on a filter, washed, and dried, was redissolved in dilute alcohol, and recovered by spontaneous evaporation of the menstruum. A white, amorphous powder was thus obtained, of an acrid taste, soluble in alcohol, and, as above stated, giving in a high degree the frothing property to water. (*Proceed. of Am. Pharm. Assoc.* for 1856, p. 36, also *Am. Journ. of Pharm.* xxviii. 512.) Besides this acrid principle, the Trillia roots are said to contain volatile oil, gum, starch, extractive resin, and tannic acid. They are astrigent; and tonic, expectorant, and alterative properties have been ascribed to them. They have been used by the vulgar to hasten parturition. The complaints in which they are said to have proved most advantageous are the hemorrhages; but they have been used also in cutaneous affections, and externally in obstinate ulcers. Mr. Williams gave a drachm of the powdered root three times a day. Of the different species, *T. erectum* is generally esteemed most active. *T. pendulum* is referred to, in the *Peninsular and Independent Med. Journ.* (Jan. 1859, p. 187), as among the most valued indigenous plants of Michigan; being used especially in menorrhagia.

TRIPOLL Terra Tripolitana. An earthy mineral, of a whitish, yellowish, or pale straw colour, sometimes inclining to red or brown, usually friable, often adhesive to the tongue, and presenting a compact or argillaceous earth, though differing from clay by the roughness and hardness of its particles, and by not forming a paste with water. *Ventes tripoli* is said to come from Corfu. Tripoli is sometimes artificially prepared by calcining certain argillites. It is used for cleaning and polishing metals.

TRITICUM REPENS. Couch-grass. Dog-grass. Quickens. Chiendent, Fr. A perennial European plant, very common in gardens and cultivated grounds, where it is considered a troublesome weed. The root, which is the part medically used, is horizontal, creeping, jointed, about as thick as a straw or thicker, inodorous, and of an agreeable, sweetish, slightly pungent taste. It is used in some parts of Europe, in the form of decoction, as a slightly aperient and nutritive drink; and has been recommended of late in irritable bladder. Great quantities of it are said to be consumed in the hospitals of Paris. The infusion or decoction, in consequence of the sugar which it contains, is susceptible of the various fermentation, and alcohol has been obtained from it by distillation.

TUSSILAGO FARFARA. Coltsfoot. Coltsfoot is a perennial herb, with a creeping root, which early in the spring sends up several leafless, erect, simple, unifloral scapes or flower-stems, five or six inches high, and bearing appressed scale-like bracts of a brownish-pink colour. The flower, which stands singly at the end of the scape, is large, yellow, compound, with hermaphrodite florets in the disk, and female florets in the ray. The latter are numerous, linear, and twice the length of the former. The leaves do not make their appearance until after the flowers have blown. They are oblong, petiolate, cordate, angular, and toothed at the margin, bright-green upon their upper surface, white and downy beneath. The plant grows spontaneously both in Europe and North America. In this country it is found upon the banks of streams in the Middle and Northern States, and flowers in April. The whole of it is employed, but the leaves most so. They should be gathered after their full expansion, but before they have attained their greatest magnitude. The flowers have an agreeable odour, which they retain after desiccation. The dried root and leaves are inodorous, but have a rough, bitterish, mucilaginous taste. Boiling water extracts their virtues. Coltsfoot exercises light sensible influence upon the human system.
It is, however, demulcent, and is sometimes used in chronic coughs, consumption, and other affections of the lungs. The expectorant properties which it was formerly thought to possess are not obvious. The leaves were smoked by the ancients in pulmonary complaints; and in some parts of Germany they are at the present time said to be substituted for tobacco. Cullen states that he found the expressed juice of the fresh leaves, taken to the extent of some ounces every day, beneficial in several cases of scrofulous sores, and a decoction of the dried leaves, as recommended by Fuller, answered a similar purpose, though it often failed to effect a cure. The usual form of administration is that of decoction. An ounce or two of the plant may be boiled in two pints of water to a pint, of which a teaspoonful may be given several times a day.

TUTTY. Tutia. Impure Oxide of Zinc. This oxide is formed during the smelting of lead ores containing zinc. It is deposited in the chimneys of the furnaces, in the form of incrustations, moderately hard and heavy, and studded over with small protuberances, of a brownish colour on the outside, and yellowish within. As it occurs in commerce, the pieces occasionally present a bluish cast, from the presence of small particles of metallic zinc. Sometimes a spurious substance is sold for tutty, consisting of a mixture of blue clay and copper filings, made into a paste with water, and dried on an iron rod. It is distinguished from the genuine tutty by its diffusing in water and exhaling an earthy smell, and by its greater friability. Tutty is used as an external application only, being employed as a desiccant in excoriations. To fit it for medicinal use it must be reduced to fine powder, which is dusted over the affected part, or applied in the form of ointment. It has been very properly dismissed from the Edinburgh official list; its use being superseded by that of the pure oxide.

ULTRAMARINE. This fine blue pigment was formerly obtained from lapis lazuli, or lazulite, a mineral of Siberia. It is now prepared artificially by mixing equal parts of sulphur, carbonate of soda, and silica, adding enough solution of soda to dissolve the silica, and rapidly igniting the mixture. A bluish-green mass results, which becomes blue by ignition in contact with air. It is thought to be a compound of the silicates of alumina and soda with sulphuret of sodium. (Pharm. Journ., xi. 280.) It is very largely manufactured at Nuremberg, in Germany. (See Am. Journ. of Pharm., xxviii. 416.)

UMBER. Terra Umbria. A mineral of a fine compact texture, light, dry to the touch, shining when rubbed by the nail, and of a fine pale-brown colour, which changes to a peculiar beautiful deep-brown by heat. According to Klaproth, it contains 18 parts of silica, 5 of alumina, 48 of oxide of iron, 20 of manganese, and 14 of water in 100. Burnt umber, as well as the mineral in its unaltered state, is used in painting. Theumber of commerce is said to be brought chiefly from the island of Cyprus.

UPAS ANTIAR and UPAS TIEUTE. Under these names, two poisons have long been used by the natives of Java and other East India islands for poisoning their arrow heads; and very exaggerated notions have prevailed among the people of the Western World in relation to the tremendously destructive power over animal life of the upas tree in Java, from which it was supposed that the poison was derived. The tale was told that birds and animals perished when within the influence of its exhalations, and that man himself, when on its near vicinity at the peril of life. All such accounts have proved to be fabulous; but there is no doubt as to the exceedingly poisonous character of the arrow poison to which reference has been made. It seems now to be pretty well determined that the active ingredient of the upas antiar is a gum-resinous exudation proceeding from incisions in the trunk of the Antiaria toxocaria, a large tree belonging to the Urticaceae, growing in Java, Celebes, and the neighbouring islands, and described in Lindley’s Flora Medica (p. 301). Like certain species of Rhus, this plant exhales an aeriform matter, which very unpleasantly affects many of those who approach it, causing eruptions upon the skin and exterior swelling, while others seem altogether insensible to its influence. The juice is mixed with various substances which probably have little other effect than to give a due consistence to the poison. This, whether taken internally or introduced into the system through a wound, acts with extreme violence, producing vomiting, with great prostration, a feeble irregular pulse, involuntary evacuations, and convulsive movements, which are soon followed by death. Brodie, who made experiments with the poison on animals, could observe no sign of special action on the brain, and believed that death was produced by its action upon the heart, which ceased to beat before respiration ceased, and after death was found full of blood, differing in both these respects from its condition under ordinary narcotic poisoning. In other words, the poison seems to rank with digitalis, tobacco, and aconite, rather than with opium, belladonna, &c. From a chemical examination by Pelletier and Caventou, it appears that the antiar owes its activity to a peculiar principle which they named antiarin, crystallizable, soluble in water and alcohol, but scarcely so in ether, and consisting of carbon, hydrogen, and oxygen, with the formula C_{14}H_{20}O_{4}. (See Am. Journ. of Pharm., Sept. 1863, p. 474.)

The **urate** is even more poisonous than the **antiar**. This is said to be obtained from a climbing woody plant, growing exclusively in Java, and belonging to the genus Strychnos, specially designated by Leschenault as *Strychnos Tietze*. It is from the bark of the root, according to this author, that the poison is prepared. A decoction of the bark is concentrated to the consistence of syrup, then mixed with onions, garlic, pepper, &c., and allowed to stand till it becomes clear. Leschenault, having dipped the point of an arrow in the poison and allowed it to dry, pricked a chicken with it, which died in a minute or two in violent convulsions. MM. Delilie and Magendie found that the poison had not lost its strength in four years. (Hammond, *Am. Journ. of Med. Sci.*, Oct. 1860, p. 366.) A gentleman of Berlin took 3 grains of the poison, apparently for the relief of headache. This disappeared, but a feeling of oppression of the stomach came on, with stiffness along the spine, in half an hour, succeeded by a feeling as of a violent shock through the system, spasmodic contraction and rigidity of the muscles, loss of speech, difficulty of deglutition; in short, with all the symptoms of a poisonous dose of nux vomica. He recovered under the use of emetics followed by opiates. (Chemist and Druggist, May 15, 1863.) In fact the poison has upon analysis been found to contain strychyna, as might have been suspected from its origin.

Dr. Wm. A. Hammond made some experiments with a poisonous substance brought by Dr. Ruschenberger from Singapore, which proved to have the combined effects of the two poisons above mentioned, both diminishing directly the power of the heart, and causing tetanic spasms of the muscles; suggesting the idea that it might be a mixture of the antiar and tietze; but Dr. Hammond seems, from other considerations, to have been led to the opinion that it had a different origin from either. (*Am. Journ. of Med. Sci.*, Oct. 1860, p. 371.)

**URATE OF AMMONIA.** *Ammonia Uras.* \((NH_4O,HO + NCHOH_2O_4)\) This is an acid salt, and may be formed by digesting uric acid in solution of ammonia. Uric acid is generally obtained from the dried and powdered excrement of the boa serpent, and of other large snakes, by dissolving it in a weak solution of potassa with the aid of heat, and precipitating the uric acid from the filtered solution by muriatic acid, added in excess. Urate of ammonia is a white, amorphous, very sparingly soluble salt. It is a constituent of some varieties of guano; and the medicinal properties of that substance are attributed by some to its presence. This salt has been used with good effects by Dr. Bauer, of Germany, as an external application, in the form of ointment, in chronic cutaneous eruptions, and in tuberculous diseases of the lungs. The ointment is made of a scruple of the salt to an ounce of lard, and is applied to the eruptions night and morning, and, in the pectoral disease, by friction, night and morning, alternating to the back and front of the chest. (*Medico-Chirurg. Review*, July, 1852, p. 207, from Buchner’s *Repert.*). The urates should be given with caution internally, for fear of producing oxalic acid in the urine. When uric acid was given to rabbits in the dose of from thirty to forty-five grains in their daily food, Dr. Neubauer found that the urea in the urine was considerably increased, showing that the acid was transformed into urea in the economy. When, however, a large quantity of uric acid was given, the urine, in addition to an increased amount of urea, contained some uric acid, and traces of oxalic acid. (*Ranking’s Abstract*, July to Dec. 1857, p. 298.)

**UREA.** \((C_2H_7NO_3)\) This substance, the characteristic organic constituent of urine, was shown by Wöhler to be identical with the hydrated cyanate of ammonia \((NH_4NCO + HO)\), which furnishes the first example of a complex organic product artificially formed. When obtained from urine, the most convenient process is that proposed by Dr. Gregory, which consists in saturating concentrated urine with oxalic acid, dissolving in water the oxalate of urea formed, decolorizing the solution with animal charcoal, digesting it with carbonate of lime, separating the precipitated oxalate of lime by filtration, and concentrating the filtrate that crystals may form. For the mode of obtaining artificial urea, the reader is referred to chemical treatises.

Urea is in the form of four-sided prismatic crystals, colourless and free from odour when pure, somewhat resembling nitre in appearance, and having a similar saline, cooling taste. It is soluble in its weight of cold water, and in every proportion in hot water. Though without acid or alkaline reaction, it is capable of uniting with several acids, forming crystallizable compounds, having all the characters of salts. Its action on the inferior animals has recently been investigated by M. Gallois. Given to rabbits in the dose of five drachms, it acted as a poison, producing accelerated respiration, weakness of the limbs, tremblings, convulsions, tetanus, and death. Administered in the daily dose of 75 grains for three days, it passed unaltered into the urine, appearing in the secretion in 30 or 40 minutes. (*Chem. Gaz.*, July 1, 1857.)

Urea was proposed many years ago by the French physicians as a diuretic; and its use in this way has been revived by Dr. T. H. Tanner, of London. In the few cases in which Dr. Tanner tried the remedy, it acted as a powerful diuretic, without giving rise to any unpleasant symptom whatever. Prof. Mauthner, of Vienna, also bears testimony to its diuretic properties, having found it, in two cases occurring in children, promptly to remove the anasarca following scarlet fever. The dose for an adult to begin with is ten
grains every six hours, dissolved in water, flavoured with syrup; the action of the medicine being aided by the free administration of diuretics, and by keeping the skin moderately cool. (See Braithwaite's Retrospect, xxv. 161.)

B. URTICA DIOICA. Common nettle. A well-known perennial herbaceous plant, growing both in Europe and the United States, by the road sides, in hedges, and gardens. The leaves, seeds, and roots were formerly officinal. They were deemed diuretic and astringent, and were employed in nephritic complaints, hemorrhages, consumption, jaundice, worms, &c. The young shoots are boiled and eaten by the common people as a remedy in scurrvy; and the fresh plant is sometimes used to excite external irritation in cases of torpor and local palsy, the part being beaten with it till the requisite degree of action is produced. The irritant effect of the nettles, applied to the skin, is said to be owing to the presence of free formic acid in the sharp hairs. (Am. Journ. Pharm., xxii. 1851.) U. urens, or U. urens, which is an annual plant, and smaller than the former species, has similar properties, and is used for the same purposes. This species also grows wild both in America and Europe. The two plants were formerly distinguished by the names of urtica major, applied to U. dioica, and of urtica minor to U. urens. Dr. U. B. Johnson, of Marion, Alabama, has found U. urens very efficacious in uterine hemorrhage. (N. Orleans Med. and Surg. Journ., vi. 452.)

W. VALERIANATE OF BISMUTH. Bismuthi Valerianae. This salt is formed by double decomposition between solutions of tennitrare of bismuth and valerianate of soda. Valerianate of bismuth precipitates as a white powder, which is washed with water, and dried with a gentle heat. It has been recommended by Righini in neuralgia, and in painful affections of the stomach. The dose is from half a grain to two grains, repeated several times a day, and given in the form of pill.

B. VALERIANATE OF IRON. Ferrii Valerianate. Dub. This official of the late Dublin Pharmacopoeia has not been retained in the British. The following was the Dublin process. "Take of Valerianate of Soda five ounces and 164 grains [avoirdupois]; Sulphate of Iron four ounces [avoird.]; Distilled Water one pint [Imperial measure]. Let the Sulphate of Iron be converted into a persulphate, as directed in the formula for Ferri Peroxydum Hydratum, and, by the addition of distilled water, let the solution of the persulphate be augmented to the bulk of eight [fluid]ounces [Imp. meas.]. Dissolve the Valerianate of Soda in ten [fluid]ounces of the Water, then mix the two solutions cold, and, having placed the precipitate which forms upon a filter, and washed it with the remainder of the Water, let it be dried by placing it for some days rolled up in bibulous paper on a porous brick. This preparation should be kept in a well-stopped bottle." The first step in this process is to convert the sulphate of protoxide of iron into the tersulphate of sesquisoxide. Then by a double decomposition between this salt and valerianate of soda, sulphate of soda is formed in solution, and tervalerianate of sesquisoxide of iron is precipitated. The proper proportion of the reacting salts is three equivalents of valerianate of soda, and one of tersulphate of sesquisoxide of iron; and the resulting salts are three eqs. of sulphate of soda, and one of tervalerianate of sesquisoxide of iron.

Properties, &c. This salt is in the form of a dark tile-red, loose, amorphous powder, having a faint odour and taste of valerianic acid. It is insoluble in cold water, and decomposed by boiling water, which extracts all its acid, and leaves the sesquisoxide of iron behind. It is soluble in alcohol. Citrate and tartrate of iron, impregnated with oil of valerian, have been fraudulently sold for valerianate of iron. The genuine salt may be distinguished from these substitutions by being insoluble in water and soluble in alcohol, and by the action of a little dilute muriatic acid, which sets free the valerianic acid, readily recognised by its disagreeable odour, which is quite distinct from that of the oil of valerian. In relation to the modes of distinguishing the true from the spurious valerianates, see Pharm. Journ. (viii. 577) Valerianate of iron has been given in hysterical affections, complicated with chlorosis. The dose is about a grain, repeated several times a day.

B. VENETIAN RED. Bolus Veneta. A dull red ochreoy substance used in painting.

VERBASCUM THAPSUS. Mullein. This is a biennial plant, with an erect, round, rigid, hairy stem, which rises from three to six feet in height, and is irregularly beset with large, sessile, oblong or oval, somewhat pointed leaves, indented at the margin, wolly on both sides, and pubescent at the base. The flowers are yellow, and disposed in a long, close, cylindrical, terminal spike. The mullein is common throughout the United States, growing along the roads and in waste fields, and springing up abundantly in nearly clear of plant, at the most remote distance from cultivation. It is, however, generally considered as a naturalized plant, introduced originally from Europe, where it is also abundant. It flowers from June to August. The leaves and flowers have been employed. Both have a slight, somewhat narcotic smell, which in the dried flowers becomes agreeable. Their taste is mucilaginous, herbaceous, and bitterish, but very feeble. They impart their virtues to water by infusion. Mullein leaves are demulcent and emollient, and are thought to possess anodyne properties, which render them useful in pectoral complaints. On the Conti-
ment of Europe, an infusion of the flowers, strained in order to separate the rough hairs, is considerably used in mild catarrhs. Dr. Home found a decoction of the leaves useful in diarrhœa. The infusion or decoction may be prepared in the proportion of an ounce of the leaves to a pint of water, and given in the quantity of four fluidounces. Dr. N. K. Newkirk, of Bridgeton, N. J., informed the author that he had found the smoking of dried mullein leaves useful in aphonia from irritation of the larynx. The leaves are also employed externally, steeped in hot water, as a feebly anodyne emollient. An ointment is prepared from them in the recent state, and used for the same purposes. It may be made in the same manner as ointment of stramonium, by boiling the leaves in lard. It will be found advantageous to moisten them with water previously to the boiling.

VERBENA OFFICINALIS. Verbena. This is a common European weed, growing on the roadsides, in the vicinity of towns and villages. Its sensible properties do not indicate the possession of medical virtues; as it is nearly inodorous, and has only a slightly astringent, bitterish taste. By the ancients it was highly esteemed both as a medicine, and as a sacred plant employed in certain religious rites. In modern times, superstitious notions in relation to its virtues are still entertained; and the suspension of the root around the neck by a white ribbon, has been gravely recommended for the cure of scrofula. The leaves, bruised and made into a cataplasm, are used by the vulgar as a remedy in severe headache, and other local pains. The plant, however, is probably inert. An American species, V. hastata, is more bitter than the European, and is said to be emetic. It is not, however, used in regular practice. Schoepf states that the root of V. urticifolia, another indigenous species, has been advantageously used in poisoning from the Rhus Toxicodendron. It is prepared by boiling it in milk and water along with the inner bark of the white oak.

VERDITER. Two preparations of copper, employed as pigments, are known by this name in commerce, and are distinguished by the epithets of blue and green. Blue verditer is prepared in London from the solution of nitrate of copper obtained in precipitating silver by copper. According to Gray, this solution is poured hot upon whiting (carbonate of lime), and the mixture stirred every day till the liquor loses its colour, when it is decanted, and fresh portions added till the proper colour is obtained. By a process for procuring this pigment, invented by Pelletier, the solution of nitrate of copper is decomposed by quicklime, and the precipitate, after being washed, is incorporated intimately with another portion of quicklime. By the former process, a carbonate of copper is obtained; by the latter, a mixture of the hydrated oxide of copper and hydrate of lime. Green verditer is prepared by precipitating a solution of nitrate of copper by chalk or a white marl, and consists of carbonate of copper mixed with an excess of the calcareous carbonate.

VERONICA OFFICINALIS. Speedwell. Several species of Veronica, common to Europe and this country, have been medicinally employed. Of these V. officinalis, and V. Beccabunga or brooklime, are the most conspicuous. V. officinalis has a bitterish, warm, and somewhat astringent taste. Examined by Enz, it was found to contain, in the fresh juice and an extract from the herb, a bitter principle soluble in water and alcohol, but scarcely so in ether, and precipitated by the salts of lead but not by tannic acid; an acrid principle; red colouring matter; a variety of tannic acid producing a green colour with the salts of iron; a crystallizable fatty acid, with malic, tartaric, citric, acetic, and lactic acids; a soft, dark-green bitter resin; and mannite. Prof. Mayer, of N. York, in an examination of the herb, found evidences of the existence of an alkaloid, and a small quantity of a sapoaceous principle. (Am. Journ. of Pharm., July, 1863, p. 209.) The plant has been considered diaphoretic, diuretic, expectorant, tonic, &c.; and was formerly employed in pectoral and nephritic complaints, hemorrhages, and diseases of the skin, and in the treatment of wounds. The beccabunga, which is very succulent, was used in the fresh state with the view of purifying the blood, and as a remedy in scurvy. Both plants, however, are at present out of use.

VISCUM ALBUM. Mistletoe. A European evergreen parasitic shrub, growing on various trees, particularly the apple and other fruit trees, and forming a pendent bush from two to five feet in diameter. The plant is famous in the history of druidical superstition. In the religious rites of the Druids, the mistletoe of the oak was employed, and hence was afterwards preferred when the plant came to be used as a remedy; but it is in fact identical in all respects with those which grow upon other trees. The fresh bark and leaves have a peculiar disagreeable odour, and a nauseous, sweetish, slightly acrid and bitterish taste. The berries, which are white, and of about the size of a pea, abound in a peculiar viscid principle, and are sometimes used in the preparation of bird-lime, of which this principle is the basis. Mistletoe is said to be capable of vomiting and purging when largely taken. A case has been recorded by M. Gempert, in France, in which a child three years old was poisoned by eating the berries. Vomiting and prostration were produced, and on the arrival of the physician the patient was found insensible, with a fixed and somewhat contracted pupil, coldness of the skin, and convulsive movements of the extremities. An emetic brought away a considerable quantity of the berries, and the child recovered. (Ann. de Thérap., 1869, p. 38.) The plant was formerly looked upon as powerfully antispasmodic, and was Lightly
estimated as a remedy in epilepsy, palsy, and other nervous diseases; but it is now out of use. The leaves and wood were given in the dose of a drachm in substance, and of an ounce in decoction. One or more species of Viscum grow in the United States, but are little used. Dr. Henry Dye, of Texas, records several cases of children poisoned by eating the berries of a species growing on the elm, probably Viscum flaveescens of Pursh, Phoradendron flaveescens of Nuttall. (See Gray's Manual, p. 382.) The prominent symptoms were vomiting and great thirst, followed by frequent discharges of bloody mucus from the bowels, with tenesmus. One of the children was found in a collapsed state, in which death took place. Dr. Dye states also that, in other instances, as he had been informed, children had eaten the berries without any ill effect. (Memphis Med. Recorder, iv. 344.)

W. WHITING. This is essentially the same as prepared chalk, being made by the pulverization and elutriation of crude chalk. It is used as a coarse paint, and for various purposes in the arts, for which carbonate of lime is requisite. Paris white is a variety of the same material.

W. WINE, AROMATIC. Aromatic Wine. The following formula for an aromatic wine, handed to us by Prof. Procter, merits notice, if only for its extensive use. "Take of Sage, Thyme, Hyssop, Spearmint, Wormwood, Origamum, each, in coarse powder, half a troy ounce; Alcohol a fluidounce; Claret Wine two pints. Mix the Alcohol and Wine, and, having moistened the powders with a portion of the mixture, pack the mass in a percolator, and pour upon it the remainder of the menstrum. When the liquid has disappeared, add Alcohol diluted with three times its bulk of water, until a pint of filtered liquid has passed." The alcohol is added to the claret wine to give it greater stability. Though not officinal, we are informed that this wine, the formula for which was introduced from France, is much employed in this neighbourhood, and to some extent also in the U. States. It is doubtless possesses strong tonic and aromatic properties, and may be used in cases of enfeebled digestion, especially when accompanied with gastric pains and flatulence; but its chief employment is externally by way of fomentation, and as a stimulant to feebile and unhealthy ulcers. It possesses the advantage over the aromatic and tonic tinctures that it is less stimulating. The dose may be from one to four fluidrachms.

W. WINTER'S BARK. WINTERA. U.S. 1850. The Bark of Drimys Winteri. The following is introduced from Part I., because the medicine is no longer recognised in the U. S. Pharmacopoeia. The genus Drimys belongs to Polyandra Tetragnya in the Linnean system, and to the natural order Magnoliaceae (Juss.), Winteraceae (Lindley). The following is the generic character. "Calyx with two or three deep divisions. Corolla with two or three petals, sometimes more numerous. Stamens with the filaments thickened at the summit, and anthers having two separate cells. Ovaries from four to eight, changing into the same number of small, many-seeded berries." (A. Richard.) This plant, which is figured in Carson's Illustrations of Medical Botany (i. 11, pl. 5), is an evergreen tree, varying in height in size; at times rising forty or fifty feet in height, sometimes not more than six or eight feet. The bark of the trunk is gray, that of the branches green and smooth. Its leaves are alternate, petiolate, obtuse, somewhat coriaceous, entire, smooth, green on their upper surface, of a pale bluish colour beneath, with two caduceous stipules at their base. The flowers are small, sometimes solitary, but more frequently in clusters of three or four, upon the summit of a common peduncle about an inch in length, simple, or divided into as many pedicels as there are flowers. The tree is a native of the southern parts of South America, growing along the Straits of Magellan, and extending as far north as Chili. According to Martius, it is found also in Brazil. The bark of the tree was brought to England, in the latter part of the sixteenth century, by Captain Winter, who attended Drake in his voyage round the world, and while in the Straits had learned its aromatic and medicinal properties. Since that period, a bark has been occasionally employed in medicine under the name of Winter's bark; but it is now believed not to have been derived from Drimys Winteri; as it does not correspond with the specimens of the bark derived from that tree, still preserved in the cabinets of Europe. The origin of the commercial Winter's bark is unknown. The following is the description of a specimen which came into our possession many years since. It corresponds closely with Guibourt's description of commercial Winter's bark. It is in quilled pieces, usually a foot in length, and an inch or more in diameter, appearing as if scraped or rubbed on the outside, where the colour is pale-yellowish or reddish-gray, with red elliptical spots. On the inside the colour is that of cinnamon, though sometimes blackish. The pieces are sometimes flat and very large. The bark is two or three lines in thickness, hard and compact, and when broken exhibits on the exterior part of the fracture a grayish colour, which insensibly passes into reddish or yellowish towards the interior. The powder resembles in colour that of Peruvian bark. The odour is aromatic, the taste spicy, pungent, and even burning. Winter's bark was found by M. Henry to contain resin, volatile oil, colouring matter, tannic acid, several salts of potass, malaie of lime, and oxidized iron. The presence of tannic acid and oxide of iron serves to distinguish it from canella alba, with which it has often been confounded. The bark above described as commercial Win-
ter's bark is destitute both of tannic acid and oxide of iron, and cannot, therefore, be the bark examined by M. Henry.*

Medical Properties and Uses. Winter's bark is a stimulant aromatic tonic, and was employed by Winter as a remedy for scurvy. It may be used for similar purposes with cinnamon or canella alba, but is scarcely known in the medical practice of this country. The dose of the powder is about half a drachm. Another species, the Drimys Chilensis of De Candolle, growing in Chili, yields a bark having similar properties. (Carson, Am. Journ. of Pharm., xix. 81.)

WOORARI. Woorara. Wooralie. Urari. Curare. This is a powerful poison, prepared by the aborigines in the interior of British Guiana, and used for arming the points of their weapons. Various opinions have been advanced in relation to its source and preparation; but the most probable account is that of Dr. Hancock, who states, from information derived from the natives, that it is a watery extract from the bark of a gourd-like plant. It has been stated that the plant producing it is a Strychnos, and Sir R. H. Schomburgk, who claims to have seen the plant, proposes to name it Strychnos toxifera. But the facts, that the poison acts in a mode directly opposite to that of strychnin in destroying life, and that chemists have been unable to detect that alkaloid in it, are, we think, sufficient proof that Schomburgk must have been mistaken on this point. (See Pharm. Journ., xvi. 502.) It has also been conjectured that the poison from the fangs of serpents is mingled with, if it does not constitute the active ingredient of the woorari. But this is contradicted by those who have had the best opportunities of ascertaining its mode of preparation; and is also opposed by the fact, that, unlike the venom of snakes, this poison does not occasion local inflammation when inserted into a wound, but appears to act exclusively on the nervous system, through the medium of the blood. In order that it may act, it must find entrance into the circulation; and hence, when swallowed, it does not in general prove poisonous, either because it cannot penetrate the mucous membrane, or because it is altered in the stomach. It would not, however, be altogether safe to rely on its innocuousness when swallowed; for, in an empty condition of the stomach, and taken in large doses, it has been found by Dr. John W. Green and others to cause death in some animals. (Am. Med. Gaz., vi. 299.) It appears also, from the experiments of MM. Pelouze and Bernard, to be absorbed as quickly from the air-passages as when inserted into the cellular tissue, and, when thrown into the rectum, produces its peculiar effects, though very slowly. (Journ. de Pharm., Août, 1856, p. 160.)

When the poison is inserted in a wound, the animal speedily falls into stupor, and dies in a few minutes, the heart continuing to act for some time after respiration has ceased. If artificial respiration is resorted to before the heart has ceased to act, and is sustained, the animal recovers. From numerous experiments, performed by different persons, there is reason to believe that woorari acts by paralyzing the nervous centres of respiration and motion, without producing essentially any discoverable alteration in the blood or solid tissues. Its action is, therefore, directly opposite to that of strychnia; and it is said to serve as an antidote to that poison by producing relaxation of the contracted muscles. Its peculiar mode of action has even suggested its remedial use in tetanus. A horse suffering under tetanus was inoculated by Mr. Sewell with woorari. In ten minutes apparent death was produced, when the animal was revived by artificial respiration; and the symptoms of tetanus did not return, though death occurred next day, as was supposed, from over-casting. (Pharm. Journ., xvi. 504.) In several cases of tetanus in which it was tried by M. L. Vella, in an hospital at Turin, it appeared to afford relief in all, and in one case recovery took place. (Arch. Gén., Oct. 1856, p. 1.) But as we have other medicines at least equally effectual, and of which the precise strength is better known, it would not be advisable to trust a case to this remedy. It is said that chlorine and bromine neutralize entirely the effects of the poison (Ibid., p. 504); and, from the experiments of Drs. Brainard and Green, there can be little doubt that iodine has the same effect. It was ascertained by them that woorari, mixed with solution of iodine and iodide of potassium, had no effect when introduced into a wound; and that, if introduced alone, its effects were quite neutralized by subsequent injection of the solution; a cupping-glass being applied so as to prevent the absorption of the poison before the iodine could be brought into contact with

* M. Guibourt. In the third edition of his "Drugues Simples," published in 1850, gives the following description of a specimen of the true Winter's bark, presented to him by Robert Brown, and labelled "Port Famine, Captain F. King, Drimys Winteri." The bark is 3 millimetres (1/18 of an inch) thick, and covered with a greyish-white, very thin, and rather smooth epidermis. It is of a deep reddish-brown colour internally, and has a spagyric appearance, especially in the part in contact with the wood, where it appears to be formed of longitudinal, radiating, lignose layers, isolated one from the other. It has a strong odour, somewhat analogous to that of canella and slightly camphorous, and a taste in like manner very aromatic, with considerable acrimony. Another specimen brought from the Straits of Magellan, in 1840, bears a close resemblance to the above, being in quills as large as the little finger, with a thickness of 2 millimetres, and an epidermis thin, smooth, and of a whiteness strongly contrasting with the reddish-brown colour of the interior. Beneath the epidermis there is a certain number of very compact concentric layers; but most of the thickness of the bark is formed of radiating and distinct lignose layers, altogether like those of the preceding specimen. Guibourt also describes the barks of two other species of Drimys, those of D. Mexicana and D. Granotensis, growing respectively in Mexico and New Granada, both of which have considerable resemblance to the preceding.—(Tom. iii. pp. 651, 682.)
PART III.

Wrightia Antidysenterica.—Zea Mays. 1623

it. (Am. Med. Gaz., vii. 305.) Attempts have been made to isolate the poisonous principle of woorari, but without satisfactory results. Dr. Heintz succeeded in obtaining the poison in an exceedingly concentrated form, but does not appear to have separated the pure active principle. (Ibid., vii. 6.)

Since the publication of the eleventh edition of the Dispensatory, elaborate and highly interesting experiments have been made by Drs. Wm. A. Hammond and S. Weir Mitchell on the woorari poison, of which we give a brief abstract, referring for a full account of them to a communication by those gentlemen to the American Journal of the Medical Sciences (July, 1859, p. 13). The specimens operated on were of two kinds, named respectively corroval and vao, and were brought by Drs. Ruschenberger and Caldwell, of the U. S. Navy, from New Granada, S. America. 1. Woorari, variety Corroval. This was in dark-brown lumps, having the appearance of a vegetable extract, and of an intensely bitter and persistent taste. Under the microscope it presented the appearance of vegetable remains, but nothing animal. It yielded its active properties to water and alcohol, and was found to contain a peculiar alkaloid, which they propose to call corrovala, and which they ascertained to produce on the system the same effects as corroval itself. These were to some extent similar to those obtained from woorari by preceding experimenters, yet with so much difference as to lead to the conclusion, that the poison was derived from a different source. In a few minutes after the introduction of the poison through a wound, paralytic phenomena became obvious, and the animal soon died, without preliminary spasm or convulsions. But the heart, instead of continuing to act after apparent death, had entirely ceased to beat, and had quite lost its irritability, so that it could not be excited by galvanism. They inferred that the action of the poison is directly and primarily on the heart, possibly through the ganglia contained in its tissue. The capillary circulation was always arrested a minute or two before the heart's actions, which the authors ascribe to paralysis of the sympathetic. There was no evidence whatever, whether chemical or physiological, of the presence of strychnia in the poison. 2. Woorari, variety Vao or Bao. This, like the preceding, had the characters of a vegetable extract, with a large proportion of vegetable but none of animal remains. It contained the same alkaloid as the corroval, but in smaller proportion; and its effects on the system, though much feebleier than those of the other variety, were of the same general character. They inferred from their observations that it was the same poison, but in a diluted state.

WRIGHTIA ANTIDYSENTERICA. (R. Brown.) Nerium antidysentericum. (Linn.) An East India tree, belonging to the Apocynaceae, the bark of which was, about a century since, in some repute in Europe as a remedy in dysentery, diarrhoea, and febrile diseases. Though no longer used in Europe, it still retains its reputation in India among the native practitioners. Dr. Stenhouse has recently examined the seeds of this plant, and obtained from them, besides a fixed oil which they contain in large quantity, a peculiar principle called by him wrightine, which though uncrystallizable, and forming uncrystallizable compounds with the acids, has claims to be ranked with the alkaloids. Both wrightine and its salts have an extremely persistent bitterness. For further particulars in reference to it, the reader is referred to the Pharmaceutical Journal (April, 1864, p. 493).

XANTHORRHEA RESINS. Two resinous substances, the products of different species of Xanthorrhoea, have been introduced into England from New Holland. They are obtained by spontaneous exudation from the stems of the plants, which are usually shrubs. One of the resins is yellow and the other red. The yellow variety is in tears, in flatish pieces having on one side the mark of the stem, or in masses of various size and irregular shape. It has a reddish-yellow colour, resembling gamboge when broken, and when heated emits a fragrant odour like that of Tolu balsam. It contains resin, cinnaear and benzoic acids, and a trace of volatile oil, and may therefore be ranked among the balsams. When heated with nitric acid, it yields a large product of carbazotic acid. In medical properties it is said to bear a close resemblance to storax and the balsam of Tolu. A tincture, made in the proportion of two ounces to a pint of alcohol, may be given in the dose of one or two fluidrachms. The red variety resembles dragon's blood in colour, and appears to be analogous to the other variety in properties. The above account has been abridged from that of Dr. Pereira in the third edition of his Materia Medica.

ZEAS MAYS. Indian Corn. Maize. The common Indian corn of this country, analyzed by Mr. Archibald Polson, of Paisley, Scotland, yielded as the average result from three varieties, 12-16 per cent. of water, 1-67 of ashes, 8-85 of gluten, 51-37 of starch, 15-77 of husk and vegetable fibre, 4-50 of fat, and 2-70 of gum and sugar. (Chem. Gaz., June 1, 1855, p. 211.) The late Dr. Gorham, of Boston, found 1-50 per cent. of sulphate and phosphate of lime. The meal, in the form of mush, makes an excellent emollient poltice, much used in hospitals; and a gruel may be prepared from it, which is sometimes more grateful to the sick than that made from oatmeal. A fungus product sometimes attends the growth of Indian corn, commonly known as the smut, which was submitted to examination by Mr. C. H. Cressler, and found to contain the alkaloid discovered by Winckler in
ergot, and named by him secalin, now considered as a mere synonyme of propylamia. Besides the alkaloid, there were obtained a thick, viscid, fixed oil, a resin soluble in ether but not in alcohol, pectin, gluten, and a species of sugar. The morbid product may, therefore, be considered as the ergot of maize. (Am. Journ. of Pharm., July, 1861, p. 306.) The fungus has received the title of Ustilago maidis. It is said to produce abortion in cows, when the diseased grain is eaten by them; and six draehms of this ergot produced the same effect on two pregnant bitches to which it was given to test its abortifacient property. (Ibid., Sept. 1861, p. 413; from Annal. Med. Vet. Belg.)

ZEDOARY. Radix Zedoaria. There are two kinds of zedoary, the long and the round, distinguished by the old official titles of radix zedoaria longae, and radix zedoaria rotunda; the former produced by the Curcumina Zedoaria of Roxburgh, the latter, as some suppose, by the Curcuma rotunda of Linn., but, according to others, by the Curcuma Zerumbet of Roxburgh. Both kinds come from the East Indies. The zedoary is in slices, from an inch and a half to three inches in length, and from half an inch to an inch thick, obtuse at the extremities, and exhibiting the remains of the radical fibres. The round is also usually in slices, which are the sections of a roundish root, ending in a point beneath, and divided longitudinally into two parts, each of which is flat on one side, convex on the other, and heart-shaped in its outline. Sometimes the root of the latter variety is entire, and sometimes in quarters instead of halves. It is marked with circular rings on the convex surface, and, like the former, with small projecting points which are the remains of radical fibres. Both are grayish-white on the outside, yellowish-brown within, hard, compact, of an agreeable aromatic odour, and a bitterish, pungent, camphorous taste. The round, however, is less spicy than the long. They yield a volatile oil when distilled with water. Zedoary is a warm, stimulating aromatic, useful in flatulent colic and debility of the digestive organs. It is not now employed, as it produces no effects which cannot be as well or better obtained from ginger. The dose is from ten grains to half a draehm. W.

ZERUMBET. Cassumuniar. Under these names an East India root was formerly used, having some analogy in sensible and medical properties to ginger, and ascribed to the Zingiber Zerumbet of Roscoe. Some consider the cassumuniar as a distinct root, and refer it to the Zingiber Cassumuniar of Roxburgh. The difference of opinion is of little importance, as neither of the roots, supposing them not to be the same, is at present to be found in the markets. By some authors the zerumbet has been erroneously confounded with the round zedoary. Geiger describes it as in pieces of the size of a fig or larger, externally grayish-brown and wrinkled, internally yellowish, hard and tough, of a biting aromatic taste, and a spicy odour.

ZIZYPHUS VULGARIS. Lamarck. Rhamnus Zizyphus. Linn. A shrub, or small tree, growing on the shores of the Mediterranean, and cultivated in Italy, Spain, and the south of France. The fruit is the part used. This consists of oval drupes, of the size of a large olive, with a thin, coriaceous, red or reddish-brown skin, a yellowish, sweet, acidulous pulp, and an oblong, pointed stone in the centre. These have the official name of jujuba. By drying, their pulp becomes softer and sweeter, and acquires a vinous taste, evincing the commencement of fermentation. They are nutritive and demulcent, and are used in the form of decoction in pectoral complaints. Jujube paste consists, properly, of gum arabi and sugar, dissolved in a decoction of this fruit, and evaporated to the proper consistence. As a demulcent, it is in no respect superior to a paste made with gum arabic and sugar alone; and the preparation commonly sold in this country under the name, contains in fact none of the fruit.

The fruits of two other species of Zizyphus, Z. Lotus, growing in the north of Africa, and Z. Jujuba, a native of the East Indies, possess properties similar to those of the first-mentioned species, and are used as food by the inhabitants of the countries where they grow.
APPENDIX.

I. ART OF PRESCRIBING MEDICINES.

The physician should be acquainted not only with the properties of medicines, and the diseases to which they are respectively applicable, but also with the art of prescribing them, so that they may be adapted to the peculiarities of individual patients, and, by the mode in which they are administered, may produce the greatest curative effect with the least possible inconvenience. In relation to these points, a few general rules will be useful for the guidance of the young practitioner, although much must be left to his own judgment and discretion. We shall compress the remarks which we have to offer, under the two heads of the quantity or dose in which medicines may be given, and the mode of their exhibition.

1. Dose of Medicines.—In the body of the work, the quantity has been stated in which each medicine must ordinarily be given to produce its peculiar effects in the adult patient. But there are various circumstances which modify the dose, and demand attention on the part of the practitioner.

The age of the patient is the most important of these circumstances. The young require a smaller dose than those of maturity, to produce an equal effect; and the old, though their systems are, perhaps, less susceptible to the action of medicines than those of the middle-aged, cannot bear an equally forcible impression. The following table of Gaubius, exhibiting the doses proportioned to the age, is frequently referred to.

The dose for a person of middle age being 1 or 1 drachm,
That of a person from 14 to 21 years will be 1/2 or 2 scruples,
7 to 14 " " 1 or 1/2 a drachm,
4 to 7 " " 1 or 1 scruple,
of 4 years " " 4 or 15 grains,
3 " " " 4 or 10 grains,
2 " " " 3 or 8 grains,
1 year " " 1/2 or 5 grains.

We prefer the following simple scheme of Dr. Young, extracted from Paris's Pharmacologia.

"For children under twelve years, the doses of most medicines must be diminished in the proportion of the age to the age increased by twelve; thus, at two years to 1/4; viz., \( \frac{2}{2+12} = \frac{1}{4} \). At twenty-one the full dose may be given."

To the above rule some exceptions are offered in particular medicines, which require to be given to children in much larger proportional doses than those above stated. Such are castor oil and calomel, a certain quantity of which will in general not produce a greater effect in a child two or three years old than double the quantity in an adult.

Sex, temperament, and idiosyncrasy have also an influence upon the dose, and should be kept in view in prescribing. Females usually require somewhat smaller doses than males, and persons of sanguine temperament than the phlegmatic. Constitutional peculiarities, called idiosyncrasies, often exist in individuals, rendering them more than usually susceptible or insusceptible to the action of cer-
tain remedies, the dose of which must be modified accordingly. Thus, in some persons a grain or two of calomel will excite salivation, while in others scarcely any quantity which can be safely administered will produce this effect. Sometimes, moreover, a medicine operates on an individual in a manner wholly different from its ordinary mode. In all such cases experience is the only sure guide; but the occasional existence of these peculiarities indicates the propriety of making particular inquiries in relation to the idiosyncrasies of those patients, for whom we may be called for the first time to prescribe.

Habit is another important circumstance which modifies the dose of medicines. Generally speaking, the susceptibility to the action of medicines is diminished by their frequent and continued use; and, in order to maintain a given impression, the quantity must be regularly increased. This is especially true in regard to the narcotics, which are sometimes borne in enormous doses by those habituated to their use. It is a good practical rule in prescribing, when circumstances demand the continuance, for a considerable length of time, of some particular effect, to vary the medicine, and employ successively several with the same general powers, so as not too rapidly to exhaust the susceptibility to the action of any individual remedy. Another important practical rule connected with the influence of habit is, when any medicine, which from its nature is of variable strength, has been employed for some time in increasing doses, to reduce the dose upon resorting to a new parcel, until its relative strength has been ascertained. A neglect of this precaution, in cases where the last parcel happened to be more powerful than that previously employed, has sometimes been followed by very serious consequences.

2. Mode of Administering Medicines.—This has reference both to the combination of medicines with one another, and the form in which they are exhibited.

Simplicity in prescription is always desirable, when no object is to be gained by deviating from it. Remedies should never be mixed together without a definite purpose, nor with the vague hope that, out of the number prescribed, some one may perchance produce a salutary impression. Those exceedingly complex prescriptions, formerly so much in vogue, of which the ingredients were so numerous as to render altogether impossible a reasonable estimate of their bearing on each other, or their effects on disease, have been generally abandoned by modern practitioners. The only ground upon which any of them can be justifiably retained is that, by very frequent trials, through a long course of years, and in various states of disease, their influence on the system may have been fully ascertained, so that they may be considered rather in the light of a single remedy than a compound of many. Upon this ground, however, no prudent physician would attempt to originate such combinations. In mixing medicines, we ought to proceed no further than we may be justified in doing by a clear knowledge of the properties and mutual relations of the several ingredients, and their fitness to answer some particular indication in the treatment of disease. There are certain principles upon which medicines may be advantageously combined, and which it may not be amiss to mention for the benefit of the young practitioner.

Remedies of the same general character may be given in connection, in order to increase their energy, or to render their action more certain. It has been well ascertained that substances thus combined will often act vigorously, when, severally, they would produce comparatively little effect; and it sometimes happens that, while their activity is augmented, they are at the same time rendered less irritating, as in the case of the drastic cathartics. (See Pilulee Catharticae Composite.)

Different medicines are very often mixed together, in order to meet different and coexisting indications, without any reference to the influence which they may reciprocally exert on each other. Thus, in the same patient we not frequently meet with debility of stomach and constipation of the bowels, connected
with derangement of the hepatic function. To answer the indications presented by these morbid conditions, we may properly combine, in the same dose, a tonic, cathartic, and mercurial alternative. For similar reasons we often unite tonics, purgatives, and emmenagogues, anodynes and diaphoretics, emetics and cathartics, antacids, astringents, and tonics; and scarcely two medicines can be mentioned, not absolutely incompatible with each other, which may not occasionally be combined with advantage to counteract coexisting morbid conditions.

Another very important object of combination, is the modification which is thereby effected in the actions of medicines differing from each other in properties. In this way new powers are sometimes developed, and those previously existing are greatly increased. Examples of such a result are afforded in the official powder of ipecacuanha and opium, and in the combination of squill and calomel; the former operating as a diaphoretic, the latter as a diuretic, beyond the capabilities of either of their constituents. The effects of one medicine are, in numerous instances, increased by the influence of another in augmenting the natural susceptibility of the system to its action. Thus, bitters enable cathartics to operate in smaller doses; purgatives awaken the dormant susceptibility to the action of mercury; and stimulants excite the torpid stomach, so that it will receive impressions from various medicines before inoperative. In some instances, the action of one medicine is promoted by that of another apparently of a nature wholly opposite. Thus, when calomel and opium are given in colic, the purgative operation of the former is facilitated by the relaxation of intestinal spasm produced by the latter. Medicines, in addition to the effects for which they are administered, very frequently produce disagreeable symptoms, which may be moderated or altogether prevented by combination with other medicines; and this object may usually be accomplished, without in the least degree interfering with the remediate influence desired. Thus, the griping produced by cathartics, and the nausea by these and various other medicines, may often be corrected by the simultaneous use of aromatics. To cover the disagreeable taste or odour of certain medicines, and to afford a convenient vehicle for their administration, are also important objects of combination; as upon these circumstances often depend the acceptability of the medicine to the stomach, and even the possibility of inducing the patient to swallow it. Substances should be preferred as vehicles which are calculated to render the medicine acceptable to the palate and stomach, and in other ways to correct its disagreeable effects; as syrups for powders, the aromatic waters for medicines given in the form of mixture, and carbonic acid water for the neutral salts.

But, in the mixing of medicines, care should be taken that they are neither chemically nor physiologically incompatible; in other words, that they are not such as will react on each other so as to produce new and unexpected combinations, nor such as will exert contrary and opposite effects upon the system. Thus, when the operation of an acid is desired, an alkali should not be given at the same time, as they unite to form a third substance entirely different from either; nor should a soluble salt of lime, baryta, or lead be given with sulphuric acid or a soluble sulphate, as decomposition would ensue, with the production of an inert compound. So, also, in relation to physiological incompatibility, diaphoretics and diuretics should not, as a general rule, be united with a view to their respective effects; as these are to a certain extent incompatible, one being diminished by whatever has a tendency to increase the other. There are cases, however, in which we may advantageously combine medicines with a view to their chemical reaction, as in the instance of the effervescing draught; and circumstances sometimes call for the union of remedies apparently opposite, as in the case of colic before alluded to, in which opium may be advantageously combined with purgatives. Still, such combinations should never be formed, unless with a full understanding of their effects, and a special reference to them.
Appendix.

The form in which medicines are exhibited is often an object of considerable importance. By variation in this respect, according to the nature of the medicine, the taste of the patient, or the condition of the stomach, we are frequently enabled to secure the favourable operation of remedies, which, without such attention, might prove useless or injurious. Medicines may be given in the solid state, as in the form of powder, pill, troche, or electuary; in the state of mixture, in which a solid is suspended in a liquid, or one liquid is mechanically mixed with another in which it is insoluble; or in the state of solution, under which may be included the various forms of infusion, decoction, tincture, wine, vinegar, syrup, honey, and oxymel. Of these different forms we have already treated sufficiently at large, under their respective heads, in the second part of this work.

In writing extemporaneous prescriptions, neatness, order, and precision should always be observed; as, independently of the pleasing moral effect inseparable from these principles in all things, a positive practical advantage results, in the greater accuracy which the habit of attending to them gives to the prescriber, and the comparative certainty which they afford that his directions will be strictly complied with. As a general rule, when medicines are combined in prescription, that should come first in order which is considered as the most prominent and important, next the adjuvant or corrigent, and lastly the vehicle. Sometimes, however, it is important to indicate to the apothecary the succession in which the substances should be combined, in reference to the perfection of the mixture; and this may render convenient a deviation from the order above mentioned. The physician should always be careful either to write out the full name of the medicine, or to employ such abbreviations as are not likely, by the misunderstanding of an ill-formed letter, to lead into error. Very serious and even fatal mistakes have been occasioned by a neglect of this precaution. The formulas of the several Pharmacopoeias which are detailed in this work, will serve as good examples for the guidance of the young practitioner. The following table explains the signs and abbreviations habitually used in prescriptions. The formulas afterwards given will serve to illustrate the ordinary mode of prescribing, while they exhibit combinations of medicines frequently employed in practice. W.

Appendix.

Examples of Common Extemporaneous Prescriptions.

Powders.

R Antimonii et Potassae Tartratis gr. i.
Pulveris Ipecacuanhae ſi.
Fiat pulvis.
S. To be taken in a wineglassful of sweetened water.
An active emetic.

R Hydargyri Chloridi Mitis,
Pulveris Jalape, ſ, gr. x.
Misce.
S. To be taken in syrup or molasses.
An excellent cathartic in the commencement of bilious fevers, and in hepatic congestion.

R Pulveris Jalape gr. x.
Potassae Bitartratis ſii.
Misce.
S. To be taken in syrup or molasses.
A hydragogue cathartic, used in dropsy, and in scrofulous inflammation of the joints.

R Sulphuris ſi.
Potassae Bitartratis ſii.
Misce.
S. To be taken in syrup or molasses.
A laxative used in piles and cutaneous diseases.

R Pulveris Rhei gr. x.
Magnesia 5ss.
Fiat pulvis.
S. To be taken in syrup or molasses.
A laxative and antacid, used in diarrhoea, dyspepsia, &c.

R Pulveris Aloës,
Pulveris Rhei, ſ, 5ss.
Saponis ſi.
Misce, et cum aqua fiat massa in pilulas viginti dividenda.
S. Two or three to be taken daily, at bedtime, or before a meal.
An excellent laxative in habitual constipation.

R Massae Pilularum Hydargyri,
Pulveris Aloës,
Pulveris Rhei, ſ, ſi.
Misce, et cum aqua fiat massa in pilulas viginti dividenda.
S. Three to be taken at bedtime.
An alternative and laxative, useful in constipation with deranged or deficient hepatic secretion.

R Pulveris Aloës,
Extracti Quassiae, ſ, ſi.
Oleí Anisi m x.
Syrupi q. s.

R Pulveris Scillae gr. xii.
Potassae Nitratis ſi.
Fiat pulvis, in chartulas sex dividenda.
S. One to be taken twice or three times a day in syrup or molasses.
A diuretic employed in dropsy.

R Potassae Nitratis ſi.
Antimonii et Potassae Tartratis gr. i.
Hydargyri Chloridi Mitis gr. vi.
Fiat pulvis, in chartulas sex dividendus.
S. One to be taken every two hours in syrup or molasses.
A refrigerant, diaphoretic, and alterative, used in bilious fevers; usually called nitrous powders.

R Pulveris Gualaci Resine,
Potassae Nitratis, ſ, ſi.
Pulveris Ipecacuanhae gr. iii.
Opii gr. ii.
Fiat pulvis, in chartulas sex dividendus.
S. One to be taken every three hours in syrup or molasses.
A stimulant diaphoretic, used in rheumatism and gout after sufficient depletion.

R Ferris Subcarbonatis,
Pulveris Colombae,
Pulveris Zingiberis, ſ, ſi.
Fiat pulvis, in chartulas sex dividendus.
S. One to be taken three times a day in syrup or molasses.
A tonic, used in dyspepsia and general debility.

Pills.

Misce, et fiat massa in pilulas triginta dividendus.
S. Two to be taken once, twice, or three times a day.
A laxative, tonic, and carminative, useful in dyspepsia.

R Pulveris Scillae ſi.
Hydargyri Chloridi Mitis gr. x.
Pulveris Acaecie,
Syrupi, ſ, q. s.
Misce, et fiat massa in pilulas decem dividendus.
S. One to be taken twice or three times a day.
A diuretic and alternative, much used in dropsy, especially when complicated with organic visceral disease.

R Pulveris Opii gr. iv.
Pulveris Ipecacuanhae gr. xvii.
Pulveris Acaecie,
Syrupi, ſ, q. s.
Misce, et fiat massa in pilulas duodecim dividendus.
Appendix.

S. One to be taken after each stool.
An anodyne diaphoretic, useful in dysentery and diarrhoea after the use of laxatives.

R. Pulveris Opill.
Pulveris Ippecauanhae, æ æ, gr. iii.
Hydrargyrpi Chloridi Mitis gr. vi.
Pulveris Acacie, Syrupi, æ æ, q. s.
Miscet, et fiat massa in pilulas tres dividenda.
S. One or more to be taken at bedtime, or according to circumstances.

MIXTURES.

R. Magnesia S.
Syrupi f. Sii.
Tere simul, et affunde
Aquæ Acidii Carbonici, f. Siv.
Fiat haustus.
S. To be taken at a draught, the mixture being well shaken.
An agreeable mode of administering magnesia.

R. Mannæ Sii.
Feniculi contusi Sii.
Aquæ bullentis f. Siv.
Fiat infusum et cola; dein adjice
Magnesia Carbonat. f. Sii.
Ft. mist.
S. One-third to be taken every three or four hours till it operates, the mixture being shaken.
An excellent carminative and mild laxative in flatulence and pain in the bowels.

R. Olei Ricini f. Sii.
Pulveris Acacie, Sacchari, æ æ, Sii.
Aquæ Mentheae Pipèritæ f. Siii.
Acaciam et saccharum cum fluiduncià di-midii aquæ menthæ tere; dein oleum adjice, et contere; denique aquam reliquam paulatim infunde, et omnia miscet.
S. To be taken at a draught, the mixture being well shaken.

R. Olei Ricini f. Sii.
Vitellum ovi unius.
Tere simul, et adde
Syrupi f. Sii.
Aquæ Mentheae Pipèritæ f. Siii.
Ft. hast.
S. To be taken at a draught, the mixture being well shaken.
This and the preceding formula afford convenient modes of administering castor oil, when the stomach is irritable. Any other fixed oil may be given in the same way. Half the quantity will often answer.

R. Olei Ricini f. Siss.
Tincture Opill m.xxx.
Pulv. Acacie, Sacchari, æ æ, Sii.
Aquæ Mentheae Viridis f. Siv.

An anodyne, diaphoretic, and alterative, very useful in diarrhoea, dysentery, typhoid pneumonia, and various other diseases.

R. Plumbi Acetatis, in pulv. triti, gr. xii.
Pulveris Opill gr. i.
Pulv. Acacie, Syrupi, æ æ, q. s. ut fiat massa in pilulas sex dividenda.
S. One every two, three, or four hours.
An astringent much employed in hemoptysis and uterine hemorrhage.

Acaciam et saccharum cum paululo aquæ menthæ tere; dein oleum adjice, et iterum tere; denique aquam reliquam paulatim infunde, et omnia miscet.
S. A tablespoonful to be taken every hour or two hours till it operates, the mixture being each time well shaken.
Used as a gentle laxative in dysentery and diarrhoea. It is usually known by the name of oleaginous mixture.

R. Elaterii gr. i.
Spiritus Ætheris Nitosi f. Sii.
Tinctura Scillæs,
Vini Colchici Rad., æ æ, f. Sis.
Syrupi f. Sii.
Ft. mist.
S. A tablespoonful to be taken three or four times a day in a little water.
Diuretic, used by Ferriar in dropsy.

R. Copaiba,
Spiritus Lavandulæ Comp., æ æ, f. Sii.
Mucilaginis Acacie f. Sis.
Syrupi f. Sii.
Simul tere; dein paulatim affunde
Aquæ f. Siv.
Misce.
S. A tablespoonful to be taken four times a day, or more frequently.
Given in chronic catarrh, and chronic nephritic affections. The dose must be larger in gonorrhea.

Neutral Mixture.

R. Acidi Citriçi Sii.
Olei Limonis m. i.
Simul tere, et adde
Aquæ f. Siv.
Liqua, et adde
Potassæ Carbonatis q. s. ad saturand.
Misce, et per linteum cola.

Or,
R. Succi Limonis recentis f. Siv.
Potassæ Carbonatis q. s. ad saturand.
Misce, et cola.
S. A tablespoonful to be given, with an equal quantity of water, every hour or two hours.
An excellent diaphoretic in fever.
Appendix.

**Effervescing Draught.**

R Potassae Carbonatis 3i.
Aquæ fʒiv.
Liqua.

Or,

R Potassae Bicarbonatis ʒii.
Aquæ fʒiv.
Liqua.

S. Add a tablespoonful of the solution to the same quantity of lemon or lime-juice, previously mixed with a tablespoonful of water; and give the mixture in the state of effervescence, every hour or two hours. An excellent diaphoretic and anti-emetic in fever with nausea or vomiting.

**Brown Mixture.**

Aquæ ferventis fʒiv.
Liqua, et addo
Vini Antimoni ʒii.
Tincturae Opii μ xx.
Ft. mist.
S. A tablespoonful to be taken occasionally.

Expectorant, demulcent, and anodyne, useful in catarrhal affections.

R Antimonii et Potassae Tartratis gr. i.
Syrupi Scillæ,
Liquoris Morphiæ Sulphatis, αα, fʒss.
Pulveris Acaciae ʒii.
Syrupus fʒss.
Aquæ fʒiv.
Ft. mist.
S. A tablespoonful to be taken occasionally.

An expectorant and anodyne cough mixture.

R Acidii Nitrosi fʒi.
Tincturae Opii gtt. xl.
Aquæ Camphoræ fʒvii.
Misce.

**Solutions.**

R Magnesiae Sulphatis ʒi.
Syrupi Limonis fʒi.
Aquæ Acidii Carbonici fʒvi.
Misce.
S. To be taken at a draught.

An agreeable mode of administering sulphate of magnesia.

R Potassae Nitratī ʒi.
Antimonii et Potassae Tartratis gr. i.
Aquæ fʒiv.
Liqua.
S. A tablespoonful to be taken every two hours.

A refrigerant diaphoretic, used in fevers.

R Camphoræ ʒi.
Myrrhae ʒss.
Pulv. Acaciae,
Sacchari, αα, ʒii.
Aquæ fʒvi.
Camphoram cum alcoholis paululo in pulvere tete; dein cum myrrha, acaciam, et saccharo contene; denique cum aqua paulatim instillata miscæ.
S. A tablespoonful to be taken for a dose, the mixture being well shaken.

A convenient form for administering camphor.

R Cretese Preparatas ʒiv.
Tincturae Opii gtt. viii.
Pulveris Acaciae,
Sacchari, aα, ʒi.
Aquæ Cinnamoni,
Aquæ, αα, fʒi.
Soluta simul tere, dein liquida paulatim inter terendum adjecie, et omnia miscæ.
S. A teaspoonful to be taken for a dose, the mixture being well shaken.

An antacid and alterative mixture, well adapted to infantile diarrhoea, with white stools. The dose mentioned is for a child a year or two old, and may be repeated four or six times in twenty-four hours.

R Pulveris Kino ʒii.
Aquæ bullientis fʒvi.
Fiat infusum et cola; dein secundum artem admissæ,
Cretæ Preparatæ ʒiiii.
Tincturae Opii fʒss.
Spiritus Lavandulae Compositi fʒss.
Pulveris Acaciae,
Sacchari, αα, ʒii.
S. A tablespoonful to be taken for a dose, the mixture being well shaken.

Astringent and antacid, useful in diarrhoea.

R Quinina Sulphatis gr. xii.
Acidi Sulphurici Aromatici gtt. xxiv.
Syrupus fʒss.
Aquæ Menthae Piperitae fʒi.
Misce.
Appendix.

S. A teaspoonful to be taken every hour or two hours.

INFUSIONS.

R Sennæ 3iii.
  Magnesia Sulphatis,
  Mannæ, aë, 3ss.
  Fœniculi 3i.
  Aquæ bullientis Oss.
  Macera per horam in vase leviter clauso, et cola.

S. A teacupful to be taken every four or five hours till it operates.
  An excellent purgative in febrile complaints.

R Colombæ contusæ,
  Zingiberis contusi, aë, 3ss.
  Sennæ 3ii.
  Aquæ bullientia Oi.
  Macera per horam in vase leviter clauso, et cola.

S. A wineglassful to be taken every four or five hours till it operates.
  An excellent purgative in febrile complaints.

R Spigelis 3ss.
  Sennæ 3ii.
  Mannæ 3i.
  Fœniculi 3ii.
  Aquæ bullientis Oi.
  Macera per horam in vase leviter clauso, et cola.

S. A wineglassful to be given to a child from two to four years old, three or four times a day.
  A powerful anthelmintic.

R Pulveris Cinchonæ Rubrae 3i.
  Acidi Sulphurici Aromatici f3i.
  Aquæ Oi.
  Macera per horas duodecim, subinde agitans.

S. A wineglassful of the clear liquid to be taken for a dose.
  A good method of administering Peruvian bark in cold infusion.
### Appendix.

The Imperial Standard Troy weight, at present recognised by the British laws, corresponds with the Apothecaries' weight in pounds, ounces, and grains, but differs from it in the division of the ounce, which, according to the former scale, contains twenty pennyweights, each weighing twenty-four grains.

In converting the weights of liquids heavier or lighter than water into measures, or conversely, a correction must be made for specific gravity. In converting weights into measures, the calculator may proceed as if the liquid was water, and the obtained measure will be to the true measure inversely as the specific gravity. In the converse operation, of turning measures into weights, the same assumption may be made, and the obtained weight will be to the true weight directly as the specific gravity.

FRENCH DECIMAL WEIGHTS AND MEASURES.

The French metrical system is based upon the idea of employing, as the unit of all measures, whether of length, capacity, or weight, a uniform unchangeable standard, adopted from nature, the multiples and subdivisions of which should follow in decimal progression. To obtain such a standard, the length of one-fourth part of the terrestrial meridian, extending from the equator to the pole, was ascertained. The ten-millionth part of this arc was chosen as the unit of measures of length, and was denominated metre. The cube of the tenth part of the metre was taken as the unit of measures of capacity, and denominated litre. The weight of distilled water, at its greatest density, which this cube is capable of containing, was called kilogramme, of which the thousandth part was adopted as the unit of weight, under the name of gramme. The multiples of these measures, proceeding in the decimal progression, are distinguished by employing the prefixes, deca, hecto, kilo, and myria, taken from the Greek numerals; and the subdivisions, following the same order, by deci, centi, milli, from the Latin numerals.

The metre, or unity of length, at 32°, = 39·371 English inches at 62°.
The litre, or unity of capacity, = 61·028 English cubic inches.
The gramme, or unity of weight, = 15·434 Troy grains.

Upon this basis the following tables, taken with some slight alterations from the Edinburgh New Dispensatory, have been constructed. It was ascertained by accurate examination at the London Mint, that the gramme is only 15·444 Troy grains, though sometimes stated at 15·444 grains.
Appendix.

MEASURES OF LENGTH.

The metre being at 32°, and the foot at 62°.

Though the decimal system of weights and measures was established by law in France, it was found impossible to procure its general adoption by the people, who obstinately adhered to the old poids de marc and its divisions; or, if they adopted the new weights, gave them the names of the old weights to which they most nearly approached. Thus, the kilogramme, which is equal to 18,327.160 French grains, or 2 pounds 5 gros 35.16 grains poids de marc, was divided into two parts, and the half of it called a pound. One reason for this adherence to the old weights was the convenience of division into halves, quarters, &c., of which the new were not susceptible. To obviate this difficulty the Imperial government legalized the employment of the half kilogramme as the unit of weight, under the name of pound, and allowed this to be divided into half pounds, quarters, eighths, ounces, &c., as in the old poids de marc. The new pound is distinguished by the name of metric pound, and has been adopted to a considerable extent; while the old weights are retained by some, particularly by the apothecaries and goldsmiths; so that three systems are now more or less in use in France—the original poids de marc, the decimal system, and the metric pound with its divisions. The following table represents the relative value of these different weights.
Appendix.

Of these weights, all except the French, Spanish, Tuscan, and Roman (first named in the table), are divided into parts corresponding with those of the English Apothecaries' weight. In these four, the drachm contains 72 instead of 60 grains, and the scruple 24 instead of 20 grains; but, as in the English, there are 3 scruples in the drachm, 8 drachms in the ounce, and 12 ounces in the pound.
APPROXIMATE MEASUREMENT.

For the sake of convenience, in the absence of proper instruments, we often make use of means of measurement, which, though not precise nor uniform, afford results sufficiently accurate for ordinary purposes. Of this kind are certain household implements, of a capacity approaching to uniformity, and corresponding to a certain extent with the regular standard measures. Custom has attached a fixed value to these implements, with which it is proper that the practitioner should be familiar; although their capacity, as they are now made, with the exception of the wineglass, generally somewhat exceeds that at which they were originally and still continue to be estimated.

A tea-cup is estimated to contain about four fluidounces, or a gill.
A wineglass - - - two fluidounces.
A tablespoon (cochlear magnum) - half a fluidounce.
A teaspoon (cochlear parvum) - a fluidrachm.

Small quantities of liquid medicines are often estimated by drops, each of which is usually considered equivalent to a minim, or the sixtieth part of a fluidrachm. The drop of water and of watery fluids is, on an average, about that size; but the same is by no means the case with all medicinal liquids, and the drop even of the same liquid varies much in bulk, according to the circumstances under which it is formed. This is, therefore, an uncertain mode of estimating the quantity of liquids, and should be superseded where minim measures can be had.

The results stated in the following table were obtained by Mr. E. Durand, of Philadelphia. (See Journ. of the Philadelphia College of Pharmacy, i. 169.) They may be relied on as accurate, but should be considered as indicating only the relative number of drops afforded by the several liquids mentioned; for, under other circumstances than those of Mr. Durand's experiments, entirely different results might be obtained as relates to each liquid. The preparations experimented with were those of the first edition of the U. S. Pharmacopeia.

Table, exhibiting the Number of Drops of different Liquids equivalent to a Fluidrachm.

* This table includes all the elements, although several of them are not used in medicine. It also embraces a few compounds which are not used in pharmacy, but which are inserted on account of their general importance. Excluding aridium and donarium, which have not maintained their claim to be considered as distinct metals, the present number of the elements is 66; three new metals having been discovered since the eleventh edition of the Dispensatory was published.

† By modern chemists the elements are designated by letters, called symbols. The initial letter of the name is the symbol, whenever it is distinctive; but, when several elements have names beginning with the same letter, the plan adopted is to represent one of them by the initial letter, and the rest by the initial letter with some other associated with it. Thus C stands for carbon, Ca for calcium, Cd for cadmium, Cc for cerium, Cl for chlorine, Co for cobalt, Cr for chromium, Cu for copper, &c. The use of these symbols saves time and space in designating the composition of compounds. Where a single equivalent is intended to be designated, the symbol of the element is simply given; but where several equivalents are to be represented, the symbol is preceded by a figure indicating the number. Thus C means one equivalent of carbon, 2C two equivalents, and so on. The number of equivalents is now generally denoted by a small depressed figure following the symbol; and this plan has been adopted in the above table. The group of letters and figures, thus used to denote the composition of any compound, is called the formula of such compound. The symbols given are those of Berzelius, and should not be varied from, for fear of destroying their usefulness by creating confusion.

* Niobium and pelopium were alleged to exist in the Bavarian and North American columbites. Recently, however, M. H. Rose has announced that they are the same, and proposes to retain the name niobium. It is not contended that the peculiar metal of the columbites is different from that discovered in 1801 by Hatchett; and, therefore, as justly remarked by Prof. A. Connell, of St. Andrews, it should be called columbium, the name given to it by its discoverer, and the name niobium should be abandoned. (Philos. Mag., June, 1854, p. 461.)

B.
### IV. TABLES

**SHOWING THE SPECIFIC GRAVITY CORRESPONDING WITH THE SEVERAL DEGREES OF HYDROMETERS IN USE.**

Bâume’s hydrometer is usually employed. In this instrument, the sp. gr. of distilled water is assumed as the zero of the descending scale, in relation to fluids heavier than itself, and as 10 on the ascending scale in relation to lighter fluids. In the following tables, the specific gravity of liquids is given, corresponding with the several degrees of this hydrometer. The first column of specific gravities is taken from the French Codex, and is, therefore, of high authority. The second is the one given in previous editions of this work, taken from Duncan’s Edinburgh Dispensatory (A.D. 1830), and based on the calculations of Huss. The third column was calculated by Mr. Henry Pemberton, of Philadelphia, in 1851, and is recognised by the Philadelphia College of Pharmacy. The figures in this column correspond with the degrees of the hydrometers prepared by Dr. W. H. Pile, of this city, which may be relied on for their accuracy.

*For Liquids lighter than Water.*

The following formulas, furnished by Dr. Pile, may prove useful by enabling any one to calculate the sp. gr. corresponding with the several degrees of Baumé's hydrometer, and, conversely, the degree of Baumé corresponding with the sp. gr.

1. For Liquids lighter than Water. The following formulas give the sp. gr. as represented in the first column in the foregoing table; or, the specific gravity being known, gives the corresponding degree of Baumé.

\[
\frac{144}{B^\circ + 134} = \text{sp. gr.}; \quad \text{and} \quad \frac{144}{\text{sp.gr.}} - 134 = B^\circ.
\]

The following formulas apply to the third column of specific gravities.

\[
\frac{140}{B^\circ + 130} = \text{sp. gr.}; \quad \text{and} \quad \frac{140}{\text{sp.gr.}} - 130 = B^\circ.
\]

2. For Liquids heavier than Water. For the first column, \(\frac{144}{B^\circ + 134} = \text{sp. gr.}\), and \(\frac{144}{\text{sp.gr.}} = B^\circ\); for the third, \(\frac{145}{B^\circ + 135} = \text{sp. gr.}\), and \(145 = \frac{145}{\text{sp.gr.}} = B^\circ\).
Appendix.

Gay-Lussac's centesimal alcoholometer is applicable only to alcohol. The scale of this instrument is divided into 100 unequal degrees, the zero corresponding to pure water, and 100° to absolute alcohol; and every intermediate degree expresses the percentage of pure alcohol, by measure, contained in the liquors examined. Thus, when the instrument stands at 40° in any alcoholic liquid, it indicates that 100 measures of the liquid contain 40 of pure alcohol and 60 of water. But, as it was graduated for the temperature of 59° of Fahrenheit, the liquors to be tested should be brought to that temperature. Tralles' centesimal alcoholometer is the one used by the U.S. Government in gauging the strength of spirit; and is generally employed in this country by distillers and wholesale dealers in the purchase and sale of alcoholic liquors. The scale of this instrument is like Gay-Lussac's divided into 100 unequal parts, each corresponding to the percentage by volume of pure alcohol contained in the liquors examined. As the sp. gr. of water is considered as unity at its temperature of greatest density 39.8° F., and the degrees of this scale are calculated for 60° F., the zero, corresponding to the density of water, will represent a sp. gr. of .9991.

The following table of Tralles gives the percentage of alcohol by measure corresponding with the specific gravity. Under alcohol in the first part of this work (page 72) a table of the percentage by weight corresponding with the sp. gr. is given. By means of these tables, in connection with the alcoholometer, every problem that can arise in reference to the strength of spirituous liquors can be solved; and by the appended table, giving the value of Baumé's degrees in those of Tralles, the facility is still further extended.

Alcoholmetrical Table of Tralles.

V. CORRESPONDENCE BETWEEN DIFFERENT THERMOMETERS.

In Fahrenheit's thermometer, which is universally employed in this country and Great Britain, the freezing point of water is placed at 32°, and the boiling point at 212°, and the number of intervening degrees is 180.

The centigrade thermometer, which has long been used in Sweden under the name of Celsius's thermometer, and is now most generally employed on the continent of Europe, marks the freezing point zero, and the boiling point 100°.

In Reaumur's thermometer, used in France before the revolution, the freezing point is at zero, and the boiling point at 80°.

In De Lisle's thermometer, used in Russia, the graduation begins at the boiling point, which is marked zero, while the freezing point is placed at 150°.

From the above statement, it is evident that 180 degrees of Fahrenheit are equal to 100° of the centigrade, 80° of Reaumur, and 150° of De Lisle; or 1 degree of the first is equal to \( \frac{9}{5} \) of a degree of the second, \( \frac{4}{9} \) of a degree of the third, and \( \frac{5}{6} \) of a degree of the last. It is easy, therefore, to convert the degrees of one into the equivalent number of degrees of the other; but, in ascertaining the corresponding points upon the different scales, it is necessary to take into consideration their different modes of graduation. Thus, as the zero of Fahrenheit is 32° below the point at which that of the centigrade and of Reaumur is placed, this number must be taken into account in the calculation. The following propositions will embrace all the cases which can arise in relation to the three last-mentioned thermometers. That of De Lisle is seldom or never referred to in works which are read in this country.

1. If any degree on the centigrade scale, either above or below zero, be multiplied by 9 and divided by 5, or if any degree of Reaumur above or below zero be multiplied by 9 and divided by 4, the quotient will, in either case, be the number of degrees above or below 32°, or the freezing point of Fahrenheit.

2. The number of degrees between any point of Fahrenheit's scale and 32°, if multiplied by 5 and divided by 9, will give the corresponding point on the centigrade; if multiplied by 4 and divided by 9, will give the corresponding point on the scale of Reaumur.

3. Any degree of the centigrade multiplied by 4 and divided by 5, will give the corresponding degree of Reaumur; and, conversely, any degree of Reaumur multiplied by 5 and divided by 4, will give the corresponding degree of the centigrade.
